FORTY-NINTH SESSION OF THE IPCC Kyoto, Japan, 8 - 12 May 2019

> IPCC-XLIX/INF. 1, Rev.3 (08.V.2019) Agenda Item: 4 ENGLISH ONLY

ADOPTION AND ACCEPTANCE OF THE "2019 REFINEMENT TO THE 2006 IPCC GUIDELINES FOR NATIONAL GREENHOUSE GAS INVENTORIES"

Collated comments from Governments on the Final Draft Report and Authors' responses

(Submitted by the Co-Chairs of the Task Force Bureau)

Confidential – This document is being made available in preparation of the Forty-Ninth Session of IPCC only and should not be cited, quoted, or distributed

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
					The ToR for the Refinement called for a clarification of the concept of "anthropogenic emissions and removals" in Volume 1, Chapter 1. Any such clarification should be evidence-based and need not be limited to "natural disturbances". Major disturbances causing significant inter-annual variability can be non-anthropogenic, but can also be human-induced. For example, the ignition of most forest fires, regardless of the scale or location (managed or unmanaged land) is due to human activities. Land management (including			
1435	1	1	60	64	fire suppression regimes) can have a major influence on the frequency and magnitude of extreme events and peat fires are most often facilitated by human activities such as drainage and land-use change. There Appears to be insufficient evidence base for linking the estimation of anthropogenic (versus non-anthropogenic) emissions on managed land solely to "inter-annual variability".	EU	Accepted	Updated.
1437	1	1	61	61	The term "LULUCF" is not used in Chapter 2, Volume 4.	EU	Accepted	Changed accordingly.
1439	1	1			We think that flexibility regarding the setting up and/or implementation of institutional arrangements is essential and we do not see the need for a common definition of 'good practice' as there can be many different good practices in different countries. Having said this, the only reference to 'good practice' in the chapter is in line 107 'It is considered good practice that countries maintain and where possible improve the quality (transparency, accuracy, completeness, comparability and consistency) of national GHG inventories'. We think that improving GHG inventories should be 'good practice' even if this cannot happen in specific years due to a number of possible and justified reasons. We know that inventories cannot be perfect. However, we think that institutional arrangements should support continuous inventory improvements. We would therefore suggest to rephrase line 107 as follows: 'it is considered good practice that countries aim at improving the quality (TACCC) of national GHG inventories on a continuous basis'.	EU	Accepted with modification	Agreed on change, with modification that improvement not simply be an "aim", which implies only intention, but something that is actively worked for and it should happen on a continuous basis.
1813	1	1	187	187	UK + Over seas Territories' should be changed to 'UK + Overseas Territories'	United Kingdom (of Great Britain and Northern Ireland)		Changed.
1815	1	1	187	187	The EU Monitoring Mechanism Regulation should have Geographical resolution for the geographical resolution, not 'Mainland UK'	United Kingdom (of Great Britain and Northern Ireland)	Accepted with	Text revised to clarify resolution is "Regulated installations within mainland UK".

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
						-		
					This section needs to be more complete, to be definitive. The last			
					sentence currently infers that if you burn biogenic waste without energy			
					recovery, that you don't report the CO2 at all. Why would that be correct,			
					to take a different reporting approach to the CO2 emitted from waste			
					burned (i) with energy recovery, or (ii) without energy recovery? It would			
					make no sense to do so, but the text here reads as such. Therefore please			
					specify again for combustion of biogenic waste without energy recovery			
					that the CO2 is reported as a memo item, and not within the national			
					inventory total. Further, it would be clearer - more definitive - to also			
					simply state here that all GHG emissions from the burning of the fossil-			
					component of mixed wastes are to be reported in the national inventory	United Kingdom (of		It would not be helpful to go into any detail in this values. The
					total - in Energy for EfW and in Waste for incineration without energy recovery. I realise this chapter 1 section is dealing with "burning of	United Kingdom (of Great Britain and		It would not be helpful to go into any detail in this volume. The details have to be discribed in AFOLU and/or energy sector
1915	1	1	89	95	biomass", but to make this clear point is worthwhile.	Northern Ireland)	Noted	volume.

1515		-			and the second s	5		
					Useful to add that where data are accessed from a regular source (e.g.			
					website, annual statistical release), that it is good practice to also log the			
					date on which the data were accessed for the use in the national			This chapter 1 has a focus on the organisational aspects of the
					inventory, as there are many data used in inventories where a more			national inventory system. The technical details of
					recently published dataset becomes available during the inventory	United Kingdom (of		implementation are addressed in other chapters of volume 1.
					compilation and reporting cycle, but is not used. Therefore good to state	Great Britain and		However, the note in table 1.5 was revised to indicate that the
1921	1	1	315	328	explictly the origin data date.	Northern Ireland)	modification	dataset description should include the version numer or date.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
1923	1	1	345	346	The sentence as it stands is poorly drafted and confusing. Suggest "A mechanism for the data users (e.g. SNE, inventory agency) to provide feedback to the data provider on any priorities for future improvement of the dataset, e.g. perhaps data would be more directly useful in different units."		Accepted with modification	Reworded "procedures that enable the receiving party (the data user, e.g., SNE or inventory agency) to provide feedback to the data supplier on priorities for future improvement of the data set".
1925	1	1	331	360	This section misses the opportunity to elaborate on the benefits of a DSA. Suggest that you add sentences along the lines of; "The purpose of establishing a Data Supply Agreement is that it can be beneficial for both parties - the SNE/inventory compiler and the data provider; the DSA will help to establish a secure data provision into the future, such that inventories can be compiled in a timely, efficient and consistent manner, with a clear understanding on both sides of the expected data to be delivered, the deadlines for delivery and the data quality requirements for use in the inventory. Also a DSA can assist the data provider organisation, as it formally documents the data requirements and can help to secure resources within the data provider organisation to deliver the data on time, to quality etc."	United Kingdom (of Great Britain and Northern Ireland)		Sentence added "Ideally, a DSA is arranged between the GHG inventory SNE and the data supplier stakeholder. A DSA can be beneficial for both an SNE/inventory compiler and data provider. A DSA can help secure data provision in the future. Also, a DSA can assist a data supplying organisations by establishing a formally recognized acknowledgement that can promote the allocation resources within a data supplying organisation to deliver high quality data on time. DSAs can be useful for managing a regularly updated GHG inventory."
1927	1	1	389	389	Change to either "Calculating GHG Estimates" or "Calculation of GHG Estimates"	United Kingdom (of Great Britain and Northern Ireland)		Changed in 'Calculating GHG estimates'.
1929	11	1	381	282	This paragraph is muddled english. Suggest you consider something like: "The process of preparing a national inventory will involve the use of numerous datasets, the application of a range of assumptions, expert judgements, data conversions and manipulations (e.g. aggregation/integration of data from multiple data sources). Inventory compilation and the documentation of the data inputs, assumptions and other details may be performed in a range of models, and the model outputs from across all source categories will need to be aggregated and reported in a consistent national dataset. (See Volume 1, Chapter 2 for further details on models and tools typically used for inventory compilation.)"	United Kingdom (of Great Britain and Northern Ireland)	Accepted with	Simplified text and focused on reference to other chapters for guidance on documentation.

2579	1	1	448	449	The new proposed text related to GHG inventory training activities appears to impose requirements which are beyond the scope of IPCC guidance and additional clarity indicating the content is not prescriptive should be added. The introductory statement that "the tools in this section should not be considered prescriptive" (see line 369) is insufficient to address our concerns, however the following specific changes provided for this section will: "Suitably trained and/or experienced GHG inventory experts help should support the national GHG inventory system to efficiently produce high quality outputs." "Ready access to training and regular review participation can will help build national capacity"	Canada	Accepted	Text revised taking into consideration the comment.
2965	1	1	65	95	This is a good addition to the 2019 refinements. It is a concise summary of how biomass is currently accounted for within national GHG inventories. However, recommend to put more emphasis on how this accounting practice only works when assessing/reporting emissions across all source categories, or at least both Energy and LULUCF sectors. Furthermore, when reviewing individual sectors (e.g., assessing Energy sector without also assessing AFOLU), the current IPCC accounting/reporting approach for the CO2 emissions from the combustion of biomass does not hold true because the carbon/CO2 reported to LULUCF is not accounted for.	United States of America	Noted	It would not be helpful to go into any detail in this volume. The details have to be discribed in AFOLU and/or energy sector volume.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
					Though this text is an improvement toward clarifying the 'why' behind			
					IPCC accounting for biogenic CO2 in the AFOLU sector, it still is a bit			
					muddied and requires further clarification. Specifically, this paragraph			
					should also include additional text that puts more emphasis on how this			
					accounting practice (of assigning the biogenic emissions associated with			
					biomass use for energy to AFOLU) ONLY works when			
					assessing/inventorying emissions across all or at least both the AFOLU and energy sectors. It should also assert that when looking at individual			
					sectors (e.g., assessing energy sector without also assessing AFOLU), this			
					accounting method for assigning biogenic CO2 emissions to AFOLU does			
					not hold because the biogenic CO2 contribution from AFOLU-based			
					biomass combustion/conversion is not accounted for. It is imperative that			It would not be helpful to go into any detail in this volume. The
					these important disctinctions be made to eliminate further confusion on	United States of		details have to be discribed in AFOLU and/or energy sector
2967	1	1	70	88	how the IPCC views biogenic CO2 emissions.	America	Noted	volume.
					Footnote pertaining to clarification on accounting for biogenic CO2 related			
					to annual crops should be at the end of the sentence on that topic, which	United States of		
2969	1	1	76	82	ends on line 79. Currently the footnote is at the end of line 82.	America	Accepted	Corrected.
					It would be helpful to repeat here "The details of this section should not	United States of	·	
2971	1	1	157	157	be considered prescriptive."	America	Accepted	Repeated.
					Provide additional information on how to fill out and use the table, and			
					clarify or provide some examples on why the table is helpful. As is, the

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
3011111111111	70.0	- Chapter			- Comments	gount, y	пеоропосо	Name to the control of the control o
639	1	2	70	70	Suggest "required" be changed to "necessary" [it sounds less prescriptive]	New Zealand	Rejected	Authors consider the word "required" as not prescriptive.
641	1	2	82		The sentence "A network of data providers will need to provide information on an annual basis" needs to be modified to take into account national circumstances such as the country doesn't produce an annual ghg inventory, and even if it does, collection of annual data is not always necessary to enable a country to prepare a ghg inventory report annually.	New Zealand	Rejected	Data collection should be on an annual basis. And it is best to have an annual inventory process to mantain expertise, allow for improvements and track emissions. Nevertheless, in case data are missing for certain temporal periods there are methods that allow for the estimation of data gaps.
643	1	2	93	93	delete "emission" from the end of the line	New Zealand	Rejected	They are called emission inventories.
645	1	2	95	97	Suggest that the phrase "need to be estimated using higher Tier methods" be modified. The application of higher tier methods to key categories will always depend on national circumstances, and while it is highly desirable, using the phrase "need to be estimated using higher tier methods" is too strong, particularly if read in conjunction with the first part of the sentence "When starting the inventory compilation for the first time". A possible redraft would be to delete "need to be estimated using higher Tier methods" from the first sentence, with the second sentence reading: "It is good practice to use Tier one methods for non-key categories and higher tier methods for key categories if national circumstances allow (see chapter 4)". This language is consistent with that in footnote 1 which occurs in line 176 and is at the bottom of page 2.7	New Zealand	Accepted with modification	Sentence changed. "Need" changed to "Should" and added the same footnote here for consistency and so it is clear that this should be done but there is an allowance for a lack of resources.
					Change "undertake new surveys targeting inventories relevant sectors" to		Accepted with	Changed in "undertake new surveys targeting inventory
647	1	2	194	195	"undertake new surveys targeting data from relevant inventory sectors"	New Zealand	modification	relevant sectors".
649	1	2	211	211	Change "formalized in any agreement to data supply" to read "formalized in any data supply agreement"	New Zealand	Rejected	The proposed change may imply a specific type of agreement. This is more generic (e.g. MoU, LoA etc).
729	1	2	355	356	The sentence "Each inventory compiler will need to find suitable categories to aggregate confidential emissions suited to their national circumstances" should be removed from Example 2 and placed near the top Box 2.0B as a chapeau for Examples 1 and 2.	New Zealand	Accepted	Changes implemented.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
	volume	Cnapter	Fromilie	Toline	'good practice', contrary to what line 821 suggests': 'It is good practice when producing suitable activity data to follow the stepwise approach shown in Figure 2.0b.' Some reasons are: a) the decision tree is too complex and difficult to implement in practice; b) we do not agree that countries should use 'expert judgement' or 'surrogate data' in all cases. We think that there should be a distinction between key categories, for which you would expect data collection activities when activity data is missing, and non-key categories, for which it may be justified using surrogate data; c) This decision tree should also be consistent with sector-specific decision trees, where lack of activity data for key categories generally leads to an expectation of data collection activities; d) The phrasing in boxes such as 'data is satisfactory' or 'assumptions are reasonable', is in our view too vague to be 'good practice'. Thus, even if the rationale for developing a decision tree for data collection is important, we would see this decision tree as an example of how countries could approach data collection. We do not think it qualifies as 'good practice' as it stands now. We do not think it should be removed as a whole either, as some countries may find it useful with the needed modifications. For instance, distinguishing between key sources and non-key sources is very relevant. Thus, we could suggest adding 'is it a KC? Yes/No' after the box 'can the data be collected?' If Yes, then 'set up programme to collect data'; if No, then 'use surrogate data'. While expert judgement is relevant for the choice of methods and input data, we think that expert judgement by itself should be avoided as input to estimating GHG emissions. Expert judgement may be used in some cases as a last resort involving non-key categories or when the actual or surrogate data		Accepted with	There is a circularity here - how can you identify key categories if you do not have any data? Do not agree this is too complex - it has to cover the available options. Data collection is a very important part of compiling an inventory and should not be over simplified. For countries with established inventories this should not impose additional activities. The comment would be true for developed countries but for those with few resources some allowances should be made, especially when an inventory is being compiled for the first time. Text on "data satisfactory" and "assumption adequate" has been replaced with "Ensure data is complete, has uncertainty information, is transparent, consistent over time and with the sectorial definitions, and is as accurate as practical".

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
1957	1	2	1025	1026	Within this table, one key aspect of facility reporting that needs to be included as a quality criterion (I suggest under "transparency", but you may consider a different TACCC criterion as more appropriate, as there are related points made under both comparability and completeness) is thus: "Where a facility reports emissions from more than one emission source category, for example a cement kiln reporting emissions from combustion of fuels (Energy) and decarbonisation of minerals (IPPU), then the reporting of AD, EFs and emissions should enable resolution of the total GHG emissions between these different source categories." You may regard this as implicit due to the wording one of your other statements, but I think to specify this clearly will be important for some inventory compilers.	United Kingdom (of Great Britain and Northern Ireland)	Accepted with modification	Accepted but text shorten and made stronger: "• FRD should be reported at a sufficient level of disaggregation for assessment and use. For example, where a facility reports emissions from more than one emission source category, (e.g. a cement kiln reporting combustion emissions (Energy) and process emissions (IPPU)), then AD, EFs and emissions should be reported separately for these source categories."
1959	1	2	1037	1044	Two concerns with this paragraph. Firstly the provision of permits / reports for each facility and inference that the inventory agency should check each one (at least for method outliers or changes) does infer a very significant resource requirement - it certainly would do for many EU Member States for example, and I'm sure for the USA and many other countries too. Second, that last sentence basically says that it is up to the inventory agency to work directly with the facility to improve the methods. In most cases, there will be a specific regulatory or trading scheme requirement for the facility reporting, and this will be governed by a regulator for the reporting mechanism. This paragraph needs to better-reflect that the inventory agency needs to work with those regulators, and discount the facility data for use in the inventory if the data aren't good enough until the matter is resolved. At least add in reference to engagement with the regulators of the reporting mechanism in this paragraph.	United Kingdom (of Great Britain and Northern Ireland)	Accepted	Agreed the original paragraph does potentially put a burden on inventory compilers. Although in some scenario, via industry consultation it is possible for all parties such as the regulation and inventory compilers to work closely with facilities. Paragraph revised: "Where methods are used that do not meet recognised standards, a report describing facility specific methods (such as engineering approaches, site specific emission factor development etc.), measurement techniques (that deviate from standards) and assumptions should be provided to allow transparent understanding of the basis of the data. Where methods do not meet national regulatory requirements, or recognised standards, national inventory compilers should only use the data if they can be assured that that facility specific methods will result in quality data that would be equivalent to or better than those resulting from national regulatory requirements, or recognised standards. When facility specific method(s) is found to be deficient, national inventory compiler(s) is encourage to work with regulator and where possible reporting facility to better understand and resolve issues as to increase data quality".
2581	1	2	183	183	Figure 2.2: Second box on the left that says "Can the data be collected through measurements, surveys or census, considering existing resources?" should mention remote sensing and geospatial as possible method for data collection. Suggest to modify text as: "Can the data be collected through measurements, surveys, census, remote sensing or geospatial products, considering existing resources?"	Canada	Accepted with modification	Sentence rephrased (geospatial products not included).

							_	
CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
3021	1	2	1025		In Table 2.4, in "Consistency" row, after Time series demonstrates consistency," recommend adding "or if not, provision is made for achieving such consistency."	United States of America	Rejected	We assume this is consistency not comparability. This table contains goals - provision for achieving consistency is not a goal - is it the way of achieving the goal.
3023	1	2	1025	1025	In Table 2.4, in "Completeness" row, recommend replacing "facilities" with "emissions" in third line. It is the fraction of emissions, not facilities, covered that determines the completeness of the reported emissions. In many cases, a high percentage of emissions can be covered even if a relatively low percentage of facilities is covered (the "80/20 rule").	United States of America	Rejected	This completeness point is considered in the first bullet. The intent of the second bullet is for complete industry coverage.
3025	1	2	1034		After "fuels and feedstock;" recommend adding "standardized methods of measuring emissions of GHGs from vents and correlating these with activity data measurements to establish emission factors." These types of measurements and correlations are essential for many industrial source categories, such as fluorochemical production and aluminum production.	United States of America	Accepted with modification	Replaced the word 'establish' in the suggested text with 'develop'.
3027	1	2	1050		Rephrase the part on de minimis to say "If the reporting program requires a de minimis provision (for burden reduction, etc.), the deminimis should in no case be set larger than the absolute value of the uncertainty." From the GHG inventory perspective it's preferable to have no de minimus so unclear why this guidance would seem to promote it.	United States of America	Rejected	The purpose of a deminimis is to reduce reporting burden at a facility level and if allowed must be clearly stated. This is similar to the UNFCCC's NE allowance and is included in several reporting regimes. The deminimis is only applicable to facilty reporting and does NOT replace inventory reporting or IPCC's completeness criteria. An inventory compiler will need to estimate the outstanding deminimis portion, respecting IPCC and UNFCCC requirements. As presented in Figure 2.2, national inventory compiler (via activity data) should know the total for a specific source to address completeness and coverage issues araising from FRD when generating a national inventory estimates.
3027			1030	1051	unclear wife this guidance would seem to promote it.	United States of	Nejecteu	estillates.
3029	1	2	1050	1051	Under activity data, also include "information on any emissions controls"	America	Accepted	Included.
3585	1	2	960		Recommend replacing "bias is" with "errors are" for the reasons cited in the comment on line 968.	United States of America	Rejected	Bias is meant here. The issue of overall quality is included in the head of the paragraph. To clarify "accuracy" is included in line 965.
3587	1	2	967		Recommend simplifying and clarifying this paragraph to read, "The primary focus of this section is to provide guidance on integrating industrial facility data for the Energy and Industrial Processes and Product Use sectors into national GHG inventories. However, these integration concepts and guidance can be adapted to most other IPCC sectors and categories such as Waste (i.e., wastewater treatments or landfills)."	United States of America	Accepted with modification	Maybe this relates to line 973? Keeping one sentence as this is one concept, see also comment ID 1823. Change text to: "Although the primary focus of this section is to provide guidance on integrating industrial facility data for the Energy and IPPU sectors into national GHG inventories, these integration concepts and guidance can be adapted to most other IPCC sectors (e.g. Waste) and categories (e.g, wastewater treatments or landfills)".
61	1	3			estimation of uncertainty includes some equations and formula which could be difficult to users with limited experience, it would be better if a friendly use tool maybe designed to help in estimating the uncertainty, otherwise to be taken into consideration in the update of the 2006 GL software (the 2019 Refinements Software)	Egypt	Noted	Tool is already provided as an Addendum to Chapter 3. No further action needed.

381	1	3	958	958	Refinement.	Russian Federation	Rejected	provides.
					emissions expressed in percentage terms.			
					as a module (absolute value) of sum of all emissions in denominator.			
					Footnote 4 in line 662 suggests that the formula should be used "caution"			
					should be exercised in the interpretation of the results in cases where the			
					point estimate is very small when compared with the size of the			
					confidence interval (e.g. a sector or inventory where removals and			
					emissions are of similar sizes). Moreover, in the unique case the sum of			
					negative quantities is equal to the sum of positive ones, the denominator			
					in the Equation 3.2 is equal to "0" and the formula has no sense."			
					The problem with the denominator has been inherited from GPG2003,			
					where in attempt to take into account that LULUCF sector emissions could			
					have negative values (as they could represent removals of CO2 from the			
					atmosphere), a module was introduced for the summation in the			
					denominator. It was meant for individual components of the sum, not for			
					the total - this most likely was a typo overlooked during the compilation			
					and editing process. Previously, in GPG2000, the denominator did not			
					have an absolute sign around the sum.			
					Indeed, when most Annex I Parties are approaching the zero carbon net			
					economies, the use of absolute sum in denominator will lead to extremely			
					large uncertainties values (like millions) that will definitely not portray the		1	
					uncertainty of a country's net emissions and ultimately will not make any			Footnote has been amended by the following sentence: "In that

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
								Text revised to read:
								Simple approaches to estimating greenhouse gas emissions and removals may be unsatisfactory for some specific categories in some countries because they fail to capture the complexity and diversity of systems and practices, in that sector. Therefore, some inventories rely on more sophisticated approaches, using models or direct measurements. In general, models may be used to estimate those emissions or removals that cannot be easily otherwise obtained, to extend limited information to cover national emissions and removals, both spatially and temporally, or to improve the accuracy of the estimates. Model development relies on data from direct measurements and uses measured data for calibration and evaluation. However, models should be used with care. Complex models are not necessarily improvements over simple ones (e.g. carbon dioxide emissions from road transport is best estimated from fuel sold and its carbon content: no transport model will provide a better estimate although they may allocate the
								emissions to specific vehicle types and estimate improved
								emission of methane and nitrous oxide). Models are limited by
					It is not clear what this section tries to say. It needs to be made clearer to the reader. For example, it needs to say when there are no gains in using			the underlying quality of the data. Use of models will require resources for additional QA/QC and
2887	1	6	839	849	more complex methods and illustrate this by examples from the literature.	Estonia	Accepted	documentation.
3035	1	6			Verification, as referred to in these lines, is not only done in carbon markets, but for a number of other other reasons (including results-based payments). Inserting carbon markets into a discussion of QA in this way may be confusing to some. It would be better to delete the reference in lines 114 and 115 and simply include the text at the end of the third paragraph include a line at the end of the box noting that "verification" has different meanings in different contexts, and in the case of carbon markets, results-based payments, etc has a meaning more similar to the QA definition above.	United States of America	Accepted with modification	A sentence has been added at the end of the box to indicate that verification has a wide range of meanings depending where it is used.
					As the section of the			
					As there have been particular sensitivities around external stakeholders "verifying" country-reported data using atmospheric measurements, it			
					may be useful here to specify that the verification contemplated is done			
					by/with inventory compilers and understood in the inventory sense (as			
					explained in Box 6.1), as opposed to done by external stakeholders and			
3037	1	6	345	חדכ	understood in the carbon markets-related sense. (A different term, such	United States of	Accepted with	In this occasion changed from verifying to comparison. Use of verification term in this context is clarified in Box 6.1.
3037	1	ь	345	3/9	as "validation," might also be considered.	America	modification	vernication term in this context is cidfilled in Box 6.1.
					In the text, F gases are considered good candidates because they are long-			
					lived, but also in the text it is noted that there are additional challenges	United States of		Revised, noting very long N2O lifetime (as opposed to several

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
Commentib	volume	Chapter	riomine	Tollne	Comments	Country	Responses	Autilors notes
					There is a description that "the carbon in NMVOC emissions from fueling stations would typically be captured in fossil fuel consumption activity data and therefore in emissions from 1.A." in the column of explanation for 1.B. Fugitive Emissions from Fuels in Table A7.1 (new), but the carbon in NMVOC emissions from fueling stations may not necessarily be captured by the emissions from 1.A. depending on the statistical survey method. If the amount of fuel actually refueled to cars is surveyed for the fuel consumption data, the carbon included in NMVOC emitted from fueling stations is not included in the fossil fuel consumption data used for 1.A. Therefore, we suggest that the description of the explanation in this table be revised by "the carbon in NMVOC emissions from fueling stations might be included in fossil fuel consumption activity data depending on			The common IPCC methodology for estimating CO2 emissions from the combustion of liquid transport fuels is based activity data on fuel sales. The fuel sales will capture all carbon
					the scope of the statistical survey, and such carbon should be included in			contained. The fugitives are then based on the emission factors
1733	1	7	295	295	emissions from 1.A for those cases".	Japan	Rejected	provided in the guidelines.
2617	1	7	51	54	The text in section 7.1 is unclear and will create confusion for inventory compilers and reviewers as to the core purpose of inventories, i.e. the direct release of GHGs as a result of human activities. Determining CO2 from the atmospheric oxidation of precursors is an option. This section needs to be clearer in that respect, by unambiguously stating that it is sufficient to estimate GHG emissions from Volume 2-5. Going beyond would exceed the terms of reference for this report.	Canada	Noted	The revision is clear on situations where it would be appropriate to calculate indirect emissions and when it would be inappropriate. The proposed general statement would create additional confusion, rather than reduce it.
					The main natural source of nitrogen is from air. Air contains 78 to 79%			
					nitrogen. What is fuel NO (what fuel does this apply to)? If technically		Accepted with	This comment addresses an editorial issue, text has been
2619	1	7	98	99	correct as written, then it should be referenced.	Canada	modification	revised to NOx from NO.
					Indirect CO2 is not an 'input" to the atmosphere; instead it is formed in the atmosphere from precursors. The use of 'input' to the atmosphere is			It is noted that the Glossary does not include a definition of indirect emissions. Given the unequal treatment of this term it would be difficult to provide such definition. As there has been no mandate to introduce a coherent concept of indirect emissions/precursors in the whole 2006 IPCC Guidelines, it seems premature to address that comment now. Every suggestion would very likely raise a lot of comments. Furthermore, the focus in 2006 IPCC Guidelines is clearly on the term "input" which has already been extensively used in the 2006 IPCC Guidelines, including in formulas as well as capture to tables. 'Formation' was only kept mainly in those part of the text where this term has already also been used in the 2006 IPCC Guidelines. It would create very likely a range of comments if we start to change terminology already introduced by 2006 IPCC Guidelines without having a specific
2621	1	7	129		technically incorrect. Replace "CO2 input to" with "CO2 formation in".	Canada	Rejected	mandate to do that.

					source of NF3, then it is shaded out. We see Table A Summary Table as			
851	1	Annex 8A.2			being one table that is split into 6 parts, not as 6 separate tables.	New Zealand	Accepted	Changes implemented as proposed.
					Similar to the above comment, a consistent approach should be taken for			
					the header on Table B Short Summary Table (1 of 2) and Table B Short			
					Summary Table (2 of 2) (pages T11 and T12) in that NF3 should be			
					included in the header regardless of whether the sectors/categories listed			
					are sources of NF3. If the sector/category isn't a source of NF3, then it is			
					shaded out. We see Table B Short Summary Table as being one table that			
853	1	Annex 8A.2			is split into 2 parts, not as 2 separate tables.	New Zealand	Accepted	Changes implemented as proposed.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
					General comment on Vol. 1: The guidance in Vol.1 is related general and crosscutting issues, sectoral guidance is given in Volumes 2 to 5. General and crosscutting guidance should include "good practice" sparsely as detailed guidance is given in the sectoral volumes which can better reflect the specificities involved with the estimation and documentation of emissions/removals, and also for ensuring consistency of the guidance. We note that this is the case for most chapters and sections in Vol. 1. However, the sections 6.12.4 to 6.12.7 on how to choose, apply and document the use models in inventory preparation include many good	,		
					practice sentences, many relevant only in special circumstances. Please			
					evaluate the general applicability the good practice guidance given, and			Section 6.12 has been included to provide specific guidance on

93	2	4	2563		to charcoal (FAO, 2016) natural forest and forest plantation as wood for energy may differ in its productions, and most of the remainder was	Iran	Accepted	
149	2	4	1829	1829	The tier 1 EF for 1B2aiv from table 4.2.4c for non-combustion CO2 from oil refining is: 5.85 t CO2 / 1000m3 refined oil (within the confidence interval [2.9; 13.5]. According to reported IEF from Parties in 2018 CRF table submissions for 1B2aiv, we can see that among e.g. 5 Parties (4 member states and one other developped country) the IEF are bewteen 2 and 67 t/1000m3 refined oil (2; 13; 35 (FR); 41; 67). This present dispersion is widely over the maximum value of the confidence interval of the IPCC tier 1 proposed EF. The explanation of such situation is certainly due to the issue of the reporting of catalyst regeneration. For France, we currently report it in 1B2aiv (that may not be the case currently for all Parties). We can see that for the new 2019 IPCC refinements, it is recommended to report catalyst regeneration emissions in 1A1b. So the IPCC 2019 refinements should bring more reporting harmonisation. Can you confirm the analysis of this issue? Furthermore with the 2019 refinements, flaring and venting will be gathered within 1B2aiv which will make reporting more simple and harmonised.		Noted	Yes, box 4.2.2 explains, that catalyst regeneration is a thermal process and heat is used within the refinery. Therefore such emissions should be reported under 1.A.1.b. It can also be confirmed that flaring and venting are now included in 1.B.2.a.iv. Comparing CRF tables - especially in this segment - may lead to misinterpretations. To stick with your example: France reports fugitive CO2 emissions in the same range as Spain and the USA (all 2000-4500 kilotons) while Canada and Denmark reports a thousandth or even hundred thousandth part (5 to 1000 tons). This cannot only be explained with refinery capacity or used technology. As all countries passed the UNFCCC reviews several times, it seems to me that some countries included certain emissions here whereas others reported them under 1.A.1.b, 1.B.2.c or 1.B.2.d or even anywhere else. A comparison is not quite appropriate.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
151	2	4	2577		The 2019 IPCC refinements recommend: "The fugitive CH4 and N2O emissions from production of biochar to be used for energy purposes would be reported in the Energy volume, while those emitted during the biochar produced that is applied in agriculture sector would be estimated and reported following the methodologies set out in the AFOLU volume".	Country	Accepted with modification	Clarifying text on reporting added.
					This choice is quite unusual compared to the general principle of emission inventory to estimate and report emissions relating to the source (emitting activity) and not relating to the end user of the product (except for actual emissions from the activities of the user). It is also unusual compared to the other principle of reporting the related emissions during			
					the year when it is emetted. These two main principles would be no longer followed in the case of biochar applied in agriculture soils. So it would be more simple and more consistent with the usual "source oriented" approach to consider instead: "The fugitive CH4 and N2O emissions during the production of biochar are to be considered and			
					reported in the Energy volume whatever the final uses of biochar (energy purposes or agriculture soil uses). Consistently, the AFOLU volume would need to be reviewed concerning the calculation of carbon capture relating to biochar uses for agriculture soils. Maybe flexibility could be introduced, and the 2 possible options could be considered?			
385	2	1	62	63	Figure 1.1: It is proposed to increase the size of the figure, because it is	France	Accepted	Figure size increased.
387	2	4	401	401	almost impossible to read it. Equation 4.1.2: It is recommended to provide the default fraction of CO2 in the recovery gas, otherwise it is impossible to estimate emissions from underground coal mines as recommended by the Equation 4.1.2.	Russian Federation	Accepted with modification	the amount of CO2 contained in the recovered gas shoud be determined in a similar way as how the volume of methane recovery and utilization in Equation 4.1.2 is obtained, and there may be 3 approach options for the potential users to choose based on whatever sources they could get.
389	2	4	471	472	It is proposed to clarify description of Tier 1 approach to indicate that it provides global average method for calculation of methane emissions from underground mines before correction for methane utulization and flaring. The present text of Tier 1 description is misleading.	Russian Federation	Rejected	No action can be taken because comment is out of scope of 2019 Refinement.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
951 953		Chapter Annexes	938	33	Annex2:This passage does not fully reflect "Fugitive emissions from mining, processing, storage and transportation of coal". So it is suggested that "and on carbon dioxide (CO2) emissions from underground mines." be replaced by "and on carbon dioxide (CO2) emissions from underground and surface coal mines." In addition, please modify Lines 255-257 in the Overview by referring to the above. "4.1.6 Coal Exploration" does not offer enough literature support or data availability to come up with a scientific, reliable and operable methodology. There are three main problems as follows: First, there is a lack of literature support: 1) The relationship between the annual augmentation of coal resources and the fugitive emissions from coal exploration. It is true that the annual augmentation of coal resources is easier to obtain than the exploration borehole data (see 964-965 for details). However, section 4.1.6 does not provide any valid literature to prove that there is a positive or linear relationship between the annual augmentation of coal resources and the fugitive emissions from coal exploration. So it is not scientific enough to use the annual augmentation as activity data to calculate the emissions. The Tier 2 and Tier 3 approaches have the similar defects. 2) The default emission factors of Tier 1 Approach are not supported by any literature. It is merely said that they are based on expert judgment (see 1036-1037 for details), without producing any valid documentation. The relevant information about the experts involved and their professional background, logical basis for judgment, whether the results of expert judgment are peer-reviewed or externally recognized is not clear or transparent.	China	Accepted Accepted	Text has been moved to an appendix. Additionally the decision tree has been corrected.
					Tier 1 Approach counts up the annual augmentation of 'proved resources, indicated resources and inferred resources' as activity data, and applies them with the same emission factor without any distinction. However, according to line 1095-1099, there are significant differences in spacing of exploration boreholes between the three categories of resources and their	China		
955	2	4	1032	2724	Figures 4.1.4, 4.3.2 and 4.3.3, which are not clear due to low resolution, are suggested to be modified and improved.	China	Accepted	
957	2	4	1351	1352	This version updates the "decision tree" in Figure 4.2.1. In the old version, the decision tree was given to natural gas and oil systems respectively, while in the new one, the decision trees are merged. However, the decision trees in 4.1 and 4.3 of the report are given separately by the emission source type. So it is suggested to keep 4.2 structurally consistent with 4.1 and 4.3.	al:	Rejected	The current version of the "decision tree" is compiled for better representation of oil and gas industry taking into account updated Annex 4A.3 (Definition of terminologies used in Section 4.2). Unification of two separated for oil and gas "decision trees" aimed to avoid duplication similar procedures of decision making, and hence to avoid extra volume of the Guidelines.
959	2	4	2053	2054	It is mentioned here that the fugitive emissions from gas production process will be considered in Section 4.3, which (P100, lines 2553-2555), however, states that no gas methodology is specifically provided. Please give it a check and explanation.	China China	Accepted

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
1453	2	2	46		It would be most useful to include in this section "new guidance" in a box, for information purposes only, similar to that in Box 2.0A of Chapter 2, Volume 4 (AFOLU). This is because IPCC guidelines on biomass are often applied or referred to outside of the NGHGI context, for example life cycle analyses or biomass projects. Many of those applications would be usefully informed by guidance similar to that in Box 2.0A mentioned above. It could point out the potential implications arising from differences in system boundaries, sectoral boundaries, timeframes and the like. Such guidance would recognise the important role the IPCC guidance already plays beyond its immediate purpose, and could help practitioners adapt it to other contexts, avoiding the inadvertant misapplication of methodologies.	Country	Rejected	The revised text elaborates on (but does not change the meaning of) the information previously presented in the bullet points, in this section of the 2006 IPCC guidelines. There is no need to highlight this information in a box, which was already accepted to be presented in bullet format. The additional information requested by the commenter is outside of the scope of this section which deals specifically with the treatment of biomass. Any more general information on the use of IPCC guidelines can be found in Volume 1.
						EU		
1835	2	4	449	450	"Low temperature oxidation of coal" would read better than "Coal low temperature oxidation"	United Kingdom (of Great Britain and Northern Ireland)	Accepted	
1873	2	4	3127	3127	Delete one instance of "Charcoal and biochar production: it is good practice". It is said twice	United Kingdom (of Great Britain and Northern Ireland)	Accepted	
2643	2	4	2063	2065	Section states: "If none of the proposals works, a value of 32% sour gas can be applied". As stated in the footnote, the 32% value is taken as the average of the Germany (40%) and Austria (25%) sour gas shares. Given that the two countries combined produce about 0.3% of total world gas production, the suggested value of 32% is not representative of world conditions. This is also overly prescriptive for the guidelines. Suggest removing this sentence and the accompanying footnote.	Canada	Rejected	I totally agree that using this split factor should not be the very first option and the value is not representative to the whole world. However, the two sentences above explain, that compiler should attempt to determine the fraction of the gas using nationally available statistics or industry information. If no data is available, the fraction should be assumed by comparing with adjacent countries or taken from the study provided. The split factor in the footnote should be used if all other attempts fail.
2645	2	4	2290	2291	Table 4.2.7 is titled "Guidance on obtaining the activity data values required" but it doesn't offer any guidance. It simply lists the activity data values previously discussed for each industry segment. Suggest deleting "Guidance on Obtaining the" from the table title.	Canada	Accepted	
3073	2	4	843	845	Column one, row four of updated Table 4.1.7 refers to an Equation 4.1.10. However, there is no such numbered equation in the draft. The equation numbering skips from Equation 4.1.8 directly to Equation 4.1.11, omitting numbers 4.1.9 and 4.1.10.	United States of America	Rejected	Numbering of equations and tables corresponds to the IPCC 2006 Guidelines

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
3141	2	4	2946	2946	Should CO2 be CO?	United States of America	Accepted	
3143	2	4	2959	2962	Indicate which of these sources are included here	United States of	Accepted	Sentence added to clarify the sources of CO2 considered.
52.15	_		2555	2502	malada milan or these sources are malada here	America	riccepted	semence duded to siding the sources of GG2 considered.
3145	2	4	2981	2982	Here and throughout this section CtL emissions are based on syngas produced but actually think coal used would be a better factor and there might be better activity data on that at the country level, syngas produced would have to be obtained from each facility and might be confidential business information (CBI)	United States of America	Rejected	Yes we agree but the literature presents emission factors as a function of syngas produced which makes sense because it is not the coal but the amount of syngas that determines production of liquid fuels downstream. No change to the text is done
3147	2	4	2989	2989	change "feedstock combusted" to "feedstock used"	United States of America	Accepted	
3149	2	4	3096	3097	Add something about potnetial double counting in the energy fuel combustion activity, in US we adjust energy use to account for syngas production used as fuel so we would already account for CO2 emissions	United States of America	Accepted	A sentence has been added to deal with this issue and also the quality control aspect of coal use as feedstock in syngas production is already addressed in lines 3144-3147 below
3593	2	4	1	3215	Fugitive CO2 emissions from coal mining have been included for the first time in 2019 IPCC refinement report. These emissions constitute a reasonable amount of GHG emission from coal mining activities. The methodology, activity data and emission factors, should be included in the refinement guidelines to provide guidance to national inventory compilation.	India	Noted	The methodology and default emission factors have already been included in the refinement guidelines. Activity data, which are country-specific and dependent on inventory year, should not be pre-assigned by the refinement.
3705	2	4	1166	1168	Unsure that the definition of what Oil and Natural Gas System comprise all we want to include. What about abandoned wells/fields?	Norway	Accepted	
3707	2	4	1256	1256	The term waste gas is used much throughout the document - is it the sum of gas being flared, vented or leaked? Please clarify and consider to include waste gas in the glossary.	Norway	Accepted	Glossary definition added, "Waste gas: gas stream containing hydrocarbons and/or other gases that are vented or flared and not used for other purposes (e.g. production of useful energy)"
						Norway		
3709	2	4	1257	1257	Already stated above		Rejected	It is critical here to highlight the that fugitives here include venting, flaring, and leaks since there is sometimes confusion around the definition of "fugitive"
	_					Norway		
3711	2	4	1276	1287	We are not sure how this summary of practices(which may vary greatly by countries and facilities) can be useful. There is little of direct reference to reporting under specific categories	Norway	Rejected	the major part of the commented paragraph is unchanged text from 2006 GLs, which is not open for revision; 2) in 2019 refinements, flaring emission factor for difference segments are provided aggregately in each relevant segment and disaggregation could be found in Annex 4A.2.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
967	3	3	562	572	The sentence "for new operations located in developing countries that operate without significant abatement, the emission factor is 0.04 kg HFC-23/kg HCFC-22 produced" states that the emission factor is 0.04, but that for "Plants of recent design, not specifically optimised" in Table 3.28 is 0.03. So a check and revision is requested.		Accepted	We agree with the commenter that the draft emission factor revisions need additional review and clarification. The draft 2019 Refinements document included review of an additional 2007 reference by A. McCulloch. In retrospect, following the commenter's note, we recognise that the change in description and characterisation of the 0.04 emission factor on lines 562 to 564 was not correct. We have deleted the draft text that discussed "new operations located in developing countries." The 0.04 emission factor is correctly characterised in Table 3.28 as "Old, unoptimised plants." In addition, the discussion of the 0.019 emission factor, also from the McCulloch 2007 reference, should appropriately refer to use of abatement. This sentence has also been deleted, as it refers to use of abatement and should not be included for a Tier 1 default emission factor. We have confirmed that the characterisations of the emission factors appropriately reflect their intended use.
						China		
1039	3	3			General and crosscutting with IPPU, also Waste: Some fuel transformation processes use the same processes (gasification) and feedstock which are addressed in the IPPU sector (hydrogen production). Some guidance how to avoid double counting of emissions would be useful. Also reference between the sector in places where double counting could be an issue would be useful. The guidance should clarify the basic principles of reporting emissions, energy use in Energy sector, non-energy use in the IPPU sector. This is especially important as sometimes it is not that clear how and where the related emissions should be reported.		Noted	The authors note that the basic principles of reporting of emissions (e.g. Energy use in the Energy sector, NEU in IPPU) is already well-established within the 2006 GLs. Specific to the Refinement, the authors have made very significant efforts to ensure that there is sufficient text to alert compilers to the risk of gaps and double-counts, including within the new Energy-Fugitives chapter, several IPPU chapters (including: Introduction, Hydrogen, Iron and Steel). Within that text the authors have noted specific issues, such as the ability to access activity data that are disaggregated to a sufficient level to enable reporting in accordance with good practice, and also to clarify where the use of specific methodologies may be limited, in light of the methods used in other parts of the inventory (e.g. where the use of carbon balance methods in Iron and Steel production impacts upon the method options for fugitive emissions from coke production, in the Energy sector). The authors therefore consider that the guidance text will help to minimise the risk of reporting gaps and double-counts.
						Finland		

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
1041	3	3	1158	1680	In earlier guidelines, there were no mention, that CO2 emissions from biological feedstocks in IPPU sector have to be reported as a memo item. This need to report the CO2 emissions from use of biomass as feedstocks in the IPPU sector as a memo item does not appear to be included in the original draft Table of Contents /Chapter Outline as attached to the Terms of Reference for the 2019 Refinement either. Please delete the guidance to report the CO2 emissions from use of biomass as feedstocks in the IPPU sector as a memo item.	Finland	Rejected	The ToR was established to generate emission estimation and reporting guidance for Hydrogen production, and one component of this industry is the generation of biogenic CO2 from certain technologies. The proposed approach to reporting of biogenic CO2 emissions from Hydrogen production is entirely consistent with the principles established elsewhere in the IPCC GLs.
1287	3	3	770	770	Process vents are typically configured for batch/intermittent or continuous measurement(s) of the concentration.	India	Accepted	We agree that processes and therefore process vents may be batch or continuous, and the approach for concentration measurements would need to reflect this. We have revised the sentence to reflect that, as the commenter suggested, process vents may be batch or continuous in nature and therefore intermittent or continuous measurements could be made.
2647	3	3	1456	1474	CO2 emission estimation for H2 production and for ammonia production should be similar because both production processes use steam methane reforming. The carbon oxidation default factor for a Tier 1 Ammonia production estimation is set to 1.0, and could be specified for Tier 2 or 3. Suggest adding this factor and methodology to the H2 Production Tier 1 evaluation with the option to specify a different factor for Tier 2 or higher.	Canada	Rejected	The estimation method provided in the Hydrogen chapter apply only when the feedstock is completely oxidized. This is considered to be the case for all production processes yielding hydrogen as the main product. The guidance in Ch. 3.2 Ammonia production specifically covers partial oxidation reactions, and should not be used as a reference for the Hydrogen chapter in this context.
3151	3	3	1	9999	Chapter 1 (Introduction) of Volume 3 needs to be updated to reflect the new source categories in the Refinement (e.g., Hydrogen Production, Rare Earth Metals, Waterproofing of Electronic Circuits, etc.) This will affect both the text and the tables.	United States of America	Accepted	Chapter has been updated to include the new source categories.
3153	3	3	221	221	"In addition," should read as "If available,".	United States of America	Rejected	This comment refers to a tier 3 method in which measurements have to been undertaken and inventory compilers should have them documented so they need information on the technologies employed (at least for internal documentation).

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
3155	3	3	973	974	NF3 should probably be removed from the table of typically emitted compounds (3.28b) because there is already a specific Tier 1 default EF for production of NF3, and NF3 is not commonly generated as a by-product during production of other fluorochemicals.		Accepted	We agree with the commenter that the majority of NF ₃ emissions occur from the intended production of NF ₃ , and outside of intended production of NF ₃ , NF ₃ emissions are significantly less. We conducted additional analysis to review the actual contribution of NF ₃ emissions from other non-NF3 fluorochemical processes based on the available data in the U.S. EPA GHGRP. For example, in RY2016, NF ₃ emissions reported under the GHGRP were 219,000 mtCO ₂ e, approximately 218,000 mtCO ₂ e (99 percent) of the emissions were from the intended production of NF ₃ , and approximately 1,150 mtCO ₂ e (1 percent) were from other types of fluorochemical processes (i.e., non-NF ₃ processes). Over the six years of reporting data, the NF ₃ emissions from intended production is 92 percent, and the NF ₃ from other fluorochemical processes is 8 percent. With the additional review, we revised Table 3.28b to replace the NF ₃ component with the next most commonly emitted fluorinated GHG.
						United States of America		
3157	3	3	1169	1169	Insert item d. Ethylene production (Volume 3, section 3.9)	United States of America	Accepted with modification	Included in item c, as methods are the same as for methanol. Line 1178 is amended accordingly.
3159	3	3	1227	1227	change spelling of "oxidise" to "oxidize" for consistency w/rest of chapter	United States of America	Accepted	
3161	3	3	1244	1245	Table 3.29, Footnote 2, last sentence, revise first instance of "Box 4.26" to "Box 3.15" and second instance of "Box 4.26" to "Box 3.16"	United States of America	Accepted	
153	3	4	807	808	- The values for Scrap Iron and Steel in Table 4.3 make reference to Table 4 of the ISO 14404-1 and -2 standards. However, Table 4 of these standards does not mention neither Scrap Iron, nor Steel. Table 4 only suggests a value for Cold Iron i.e. 0.172 tCO2/t (0.047 tC/t) which corresponds to the value suggested for Purchased Pig Iron in Table 4.3 Material-specific carbon contents have to be given for Scrap Iron and Steel, and also for Steel Scrap which are consistent with practice. We suggest to use the value given in Annex C of standard EN 19694-2 for post-consumer scrap i.e. 0,0066 tCO2/t (0.0018 tC/t) which is based on the average of the carbon content of all the steel put on the market by EU producers in the years 2007/2008. Hence, this 0.0018 tCO2/t value should be used for both Steel Scrap and Steel (which should be renamed Carbon Steel Scrap and Carbon Steel). It is much more consistent with the actual values observed in practice than the 0.01 tC/t used for steel in the current Table 4.3.		Accepted	The text of FD has been changed accordingly as commenter proposed: in the table 4.3 Steel will be replaced with Steel Scrap and Steel.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
437	3	4	628	632	The CO2 emissions from the combustion of blast furnace gas and converter gas for different needs within an integrated iron and steel production facility have been accounted for automatically by the equation 4.9 because only blast furnace gas transferred off site is subtracted. Applying of additional methodology described in Chapter 2 Volume 2 will result in double counting.	Russian Federation	Accepted	This paragraph corresponds to Tier 1, and has been moved up.
439	3	4	721	721	CH4 should be changed to N2O	Nussian reactation	Accepted	Text has been changed accordingly
						Russian Federation		
441	3	4	2083	2084	To make more clear it may be reformulated as follows: "SBS = mass fraction of alumina produced by sintering process. The parameter can be varied from 0 to 1, where 1 is related to 100% of alumina produced by sintering process." Also, the default SBS value should be provided for Tier 1 methodology.	Russian Federation	Accepted with modification	The text has been changed as follow "mass fraction of alumina produced by sintering process (BSP and BSS). The parameter can be varied from 0 to 1, where 1 is related to 100% of alumina produced by sintering process." Default Sbs added.
443	3	4	2085	2086	There is a contradiction between statement "The parameter can be varied from 0 to 1, where 1 is related to 100% of alumina produced by sintering process" and line 2098-2099 indicating that "In case of alumina production from the nepheline ore, 100% of alumina is produced with the sintering process". It may be reformulated as follows: "SNP = mass fraction of alumina produced by sintering process. The parameter equals 1, because 100% of alumina in this process produced by sintering process."	Russian Federation	Accepted with modification	Text has been changed as per GOV reviewer comments, with minor clarifications added
445	3	4	2154	2158	Equation 4.27h CO2 emissions from carbon-bearing non-fuel materials are subtracted from the total CO2 emissions. It is contradictory to the statement that this materials may contribute to the emissions (lines 2137-2144).	Russian Federation	Accepted	Changes made to text - agree "+" used instead of "-", Corrected another incorrect symbol in the equation.
447	3	4	2161	2166	It seems that it is better to use "bauxite/limestone raw mix" and "nepheline/limestone raw mix" instead of "bauxite and nepheline ore". Otherwise, it is not clear why bauxites and nephelines contain remarkable amounts of carbonates.		Rejected	Bauxite and Nepheline ores have carbonates and it is not because of mix ore and limestone. Limestone separatelly considered in as ELC. So to avoid confusion suggested do not consider this comment. Some clarifications have been made to the text on 'ores'
						Russian Federation		
449	3	4	2192	2194	It seems that it is better to use term "potential emissions" instead of "emissions" because emissons do not actually occur in the process.	Russian Federation	Accepted with modification	Changes made to text as recommended + added notification: ", that is not emitted because some carbon absorbed by residue and stored at bauxite or nepheline residue areas",
451	3	4	2198	2208	Authors should check on the possible double counting of CO2 emissions from soda ash use in alumina production (Equation 4.27h). In equation 4.27i only mass of soda ash produced for using out of plant is accounted for (Line 2208), while in equation 4.27h the total amount of soda ash used in the sintering process is accounted for (not only soda ash purchased from other producers).	Russian Federation	Rejected	Soda ash produced for using out of plant is used out of plant. If it used at other alumina refinary it will be considered at particular alumina refinary as an input material in equation 4.27h. So There is no possible double-counting possibe.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
453	3	4	2223	2232	1. It seems that it is better to use "bauxite/limestone raw mix" and "nepheline/limestone raw mix" instead of "bauxite" and "nepheline". 2. There is a contradiction between lines 2227-2228 and line 2232. The authors propose to calculate the weighted average content of CO2, assuming 100% calcination of the carbonate, while in the equation 4.27k there is a factor (Fj) taking into account that calcination is not 100%. 3. The authors propose to calculate the weighted average content of CO2 for carbonates consumed in the kiln. Soda ash is a carbonate too, but it is accounted for separately in the equation 4.27h. It seems that it is better to indicate clearly which carbonates are meant.	Russian Federation	Accepted with modification	
455	3	4	2249	2250	It should be reformulated as "EFk = emission factor for kerogen or other carbon-bearing nonfuel raw material k, tonnes CO2/tonne carbon-bearing	Russian Federation	Accepted	Changes made as recommended.
457	3	4	2307	2314	nonfuel raw material". Needs language editing.	Russian Federation	Accepted	Changes made to text for clarity
893	3	4	375	375	"CF4" should be changed into CH4	Republic of Korea	Accepted	Text has been changed accordingly
901	3	4	430	431	In tier 2 methodology using mass balance, CH4 emissions are not necessary to be estimated since all carbon emissions are already counted as CO2.	Republic of Korea	Rejected	IPCC methodology has to cover the emissions of all GHGs, including CH4.
903	3	4	614	622	"BFG" need to be changed into "BG" followed by equations 4.9, 4.10	Republic of Korea	Accepted	Text has been changed accordingly
969	3	4	369	380	The units in Equation 4.1 and Equation 4.1A are not identical. According to the formula, the unit on the left side is in kg, and the right side is in tones. It is suggested that the unit of emissions be changed to tones in line 378.	China	Accepted	Text has been changed accordingly
1043	3	4	2669	2670	Default Tier 1 emission factor for emissions from rare earth metals production in Table 4.26 is based on information only from 4 industrial production lines. There is a risk that this emission factor is not representative and applicable as a default emission factor for all process lines. Tier 3 method presented in the guidelines requires facility specific emission factors and the use of this method is not feasible if this emission source is minor in certain countries. Proposition: move description of these two methods and emission factors to an appendix.	Finland	Rejected	While it is acknowledged that the default emission factor (EF) was based on anode carbon consumption data from 4 industrial potlines in China, these potlines are considered representative of current technology in China (ref. Cai et al 2018), and China currently represents >90% of global production. This default EF is also consistent with what is expected from first principles / mass balance calculation approach with stoichiometric ratios of carbon consumed (and hence CO2 formed) vs. RE metal formed; this was described in footnote 1, page 4.83, and has now been moved to note 'b' under Table 4.26 for clarity. The method of estimating CO2 emission factors from net anode carbon consumption is consistent with CO2 accounting approach for aluminium production. Further clarification has been made to note 'a' in Table 4.26. While a level of uncertainty is expected in estimating CO2 emissions outside China (or for other technologies), it is not expected to be greater than the uncertainty levels indicated in Table 4.26. Therefore, we believe the risk that the default EF is not representative to all process lines is manageable.

1961	3	4	207	252	Whilst this section may be greyed out and considered "out of mandate"		Accepted	The authors agree with the reviewer about the need to modify
					for any revisions, nevertheless it requires a small change to reflect that		,	this paragraph in grey.
					the new Energy-Fugitives chapter now presents the emission sources and			
					methods for fugitive releases from transformation process, including coke			
					production. It doesn't make sense that this greyed out section includes			
					reference (lines 241 to 247) to the reporting of emissions from fuel use in			
					coke production in the Energy Volume, but doesn't also mention the			
					methods and reporting of fugitive emissions in the Energy Volume too.			
					Please make it clear to compilers and amend those cross-references.	United Kingdom (of		
						Great Britain and		
						Northern Ireland)		
1963	3	4	256	454	This entire section needs to be reviewed (and much of it removed) in light		Accepted with	The comment is right, in the sense that the methodologies to
					of the decision to now include fugitive emissions from coke production		modification	estimate and report GHG emissions from combustion and
					under the new Energy Volume chapter. The IPCC approach is that coke			fugitives are included in the Energy chapter, but is incomplete
					production is an energy transformation process. Combustion is reported			because combustion and fugitives do not comprise non-fugitive
					in Energy; fugitives are now to be reported in energy. Therefore, all of the			carbonization emissions that occurs in coke oven batteries.
					relevant information - the description of the coke production			To clarify this issue the consistency between combustion and
					technologies, the combustion and fugitive emission sources - should only			fugitives (described in Energy reported under Energy) and non-
					be included in the energy volume of the inventory guidance - duplication			fugitives from carbonization (described in IPPU, reported under
					of inventory guidance across Energy and IPPU will cause confusion for			Energy), has been improved with modifications in the text
					compilers. Guidance should be in one place only for a given emission			Ziel Byjj nas seen improved with modifications in the text
					source. There is still a need to retain some residual information in IPPU			
					and to cross-reference properly, especially where methodological choices			
					/ decisions are inter-twined (e.g. some methods in Energy-fugitives will			
					have to be discounted if a carbon balance approach is used in I&S			
					including the coke works in IPPU) but the vast majority of this section			
					should be deleted, and the Energy-Fugitives chapter clearly cross-			
					referenced.	United Kingdom (of		
					referenced.	Great Britain and

Such a column would fit before or after the final two columns, which relate to each method's applicable. Such a column would fit before or after the final two columns and start-up. If this would make the table too wide, other options include: (1) replacing one or both of the final two columns with the column including the smelting technologies to which the method and that includes the final two columns with the column including the smelting technologies to which the method is applicable, or (2) creating a second table that flows on the method is applicable; or (2) creating a second table that flows on the method is applicable; or (2) creating a second table that flows on the method is applicable, or (2) creating a second table that flows on the first table), the first two columns say "Yes" indicates that these columns are not conveying much information. Although information on the applicability of each method to each technology appears in the fortness to the table, it is considerably more difficult to extract the information from a table. 3225 \$ 3 4 1234 1235						tiers but it is really focused on calculating PFC emissions from HVAEs.			caption in Decision Tree Fig 4.12 to refer to "HVAE related"
about the method for IVAEs. Or the authors could provide a modified decision tree. If keeping decision tree as-is, in would be useful to provide guidance about whether it is acceptable e.g. to combine a Ter 3 HVAE method with Ter I LVAE estimates if facility specific IVAE messurements are not available earlier than the time-series consistancy section (where it does talk about it) 3223 3 4 1234 1235 Table 4.14 as is very helpful. It would be even more helpful if it included a summary of the smelting technologies to which each method is applicable. Such a column would fit before or after the final two columns, which relate to each method's applicability or normal operations and startury. If it is would make the table too wide, other options include; I replacing one or both of the final two columns with the column including the smelting technologies to which the method is applicable, or (2) creating a second table that focuses on the applicability of each method and that includes the first three columns (repeating them from the list table), the first three columns (repeating them from the list table), the first three columns (repeating them from the list table), the first three columns (repeating them from the list table), the first two columns with the column including the smelting technologies to which the method is applicable, or (2) creating a second table that flow columns (repeating them from the list table), the first two columns say "Yes" inclicates that these columns are not conveying microwing them from the first table), the first three columns (repeating them from the list table), the first table of the first three columns (repeating them first table) and a new column with the smelling technologies to which the method is applicable. 3225 3 4 1234 1235 Consider removing the "Applicable for" columns. With almost all values information from a table. 4 1234 1235 Consider removing the "Applicable for" columns. With almost all values information from a table. 5 1236 Consider removing the "Applicable for "						Authors should consider revising tree to refer to HVAE emissions			emissions only, raher than 'total' emissions previously. In the
decision tree. If keeping decision tree as-is, it would be useful to provide guidance about whether it is acceptable e.g. in combine a Ties of HVAE method with Tier 1 LVAE estianties if facility specific LVAE measurements are not available earlier than the time-series consistancy section (where it does talk about it) 1223 Table 4.14a is very helpful. It would be even more helpful if it included a summary of the melting technologies to which each method is applicable. Such a column would fit before or after the final two columns, which relate to each method's applicability to normal operations and start- up. If this would make the table too wide, other options include; the small recommendation with a column including the smelting technologies to which the method is applicable, Quite final account of the column including the smelting technologies to which the method is applicable, Quite final account of the column including the smelting technologies to which the method is applicable, Quite final account of the column including the smelting technologies to which the method is applicable, Quite final account of the column including the smelting technologies to which the method is applicable, Quite final account of the column including the smelting technologies to which the method is applicable, Quite final account of the column including the smelting technologies to which the method is applicable, Quite final account of the column including the smelting technologies to which the method is applicable, Quite final accounts of the column including the smelting technologies to which the method is applicable, Quite final accounts of the column including the smelting technologies to which the method is applicable, Quite final accounts of the column including the smelting technologies to which the method is applicable, Quite final accounts of the column including the smelting technologies to which method accounts of the column including the smelting technologies to which the method is applicable. Quite final accounts of						calculations (not total as stated in title). There is no guidance in the tree			HVAE decision tree (Fig 4.12), question in diamond "Is there an
guidance about whether it is acceptable e.g. to combine a Tier 3 HVAE method with Tier 1 LVAE staintes of facility specific LVAE measurements are not available earlier than the time-series consistancy section (where it does talk about it) 1234 1235 Table 4.14a is very helpful. It would be even more helpful if it included a summary of the smetting technologies to which each method is applicable. Such a column would fit before or after the final two columns, which relate to each method's applicability to normal operations and startup. If this would make the table too wide, other options include: (1) replacing one or both of the final two columns, which relate to each method and that includes the first three columns with the columns including the smelting technologies to which the method is applicable, or (2) creating a second table that focuses on the applicability of each method and that includes the first three columns (moving them from the first table), the final two columns (moving them from the first table) and a new column with the smelting technologies to which the method is applicable. Option (1) may be simplest and least disruptive. The fact that all but one of the cells in the current final two columns says "me" indicates that these columns are not conveying much information. Although information on the applicability of each method to each technology appears in the footnotes to the table, it is considerably more difficult to extract the information from the footnotes than it would be to extract the information from the footnotes than it would be to extract the information from the footnotes than it would be to extract the information from the footnotes than it would be to extract the information from the footnotes than it would be to extract the information from the footnotes than it would be to extract the information from the footnotes than it would be to extract the information from the footnotes than it would be to extract the information from the footnotes than it would be to extract the informati						about the method for LVAEs. Or the authors could provide a modified			automatic HVAE termination strategy?" replaced with "Is the
method with Tier 1 LVAE estamets if facility specific LVAE measurements are not available earlier than the time-series consistancy section (where it does talk about it) 3223 3 4 1234 1235						decision tree. If keeping decision tree as-is, it would be useful to provide			technology class PFPB_MW", to be consistent with the

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
3263	3	4	2584	2588	"it is assumed that industrial rare earth facilities currently do not manufacture or pre-bake their own graphite anodes." Is this assumption based on the fact that such pre-baking has not been observed at rare earth facilities whose emissions have been measured? If so, please clarify this.		Accepted	The following sentence is added: "For example, it is assumed that industrial rare earth facilities currently do not manufacture or 'pre-bake' their own carbon anodes, but rather they purchase graphite anodes. This is the case in the Chinese rare earth metal industry in 2018 (expert opinion), given the much lower process volumes and smaller anode sizes compared to the primary aluminium industry". This is based on observation that no rare earth facilities in China manufacture or bake their own carbon anodes, rather they purchase graphite anodes from third party providers. This is based on expert opinion from IPCC Contributing Authors: Prof. Youming Yang who is an industry expert in Chinese Rare Earth Metal production and Dr Xiping Chen, who was one of the senior Chinese researchers who has worked with the local rare earth industry and measured PFCs in the two reported industrial campaigns.
						United States of America		
3265	3	4	2594	2594	In the last box on the left in Figure 4.17, recommend replacing "process data" with more precise "anode data"	United States of America	Accepted	Changes made to ext in Figure 4.17 box as identified
3267	3	4	2608	2610	Recommend replacing "uses a lower order estimate based only on" with "multiplies a default emission factor by." The method generates an estimate rather than using it, and "lower order" estimate could be interpreted to mean underestimate.	United States of America	Accepted with modification	Changes made to text, with some slight adjustments. "The Tier 1 method for calculating CO2 emissions is through multiplying a default emission factor by rare earth metal production."
3269	3	4	2642	2643	Recommend including guidance for situations where anode composition is different for different REs, such as "where the anode composition differs, replace Impa with Impi, the impurity content of the anodes used to produce each type of RE."	United States of America	Accepted	Changes made to the text as recommended
3271	3	4	2781	2782	It is unclear why RE-iron is assigned a unique emission factor. Authors should consider adding a note on how it was determined that RE-iron alloys should have a unique EF from other REs, e.g. is there a scientific reason for a different EF or is the separation just based on measurement differences? If the latter, consider whether there is enough data to support a unique EF.	United States of America	Accepted with modification	An explanation as to why RE-Fe (e.g. Dy-Fe) alloys are expected to have greater PFC generation - and therefore justify having separate emission factors (EFs) - was provided in footnote 1 of page 4.85; this footnote 1 has been further updated to provide extra clarity of the following. Due to the high melting point of these elements, they require alloying with Fe to produce a liquid metal product, which requires high temperature and high cell voltage - since PFC generation occurs at higher electrochemical potentials, these two conditions theoretically increase the risk of PFC emissions for production of RE-Fe alloys ws. other RE metals. This theory is supported by industrial measurements in Cai et al. 2018 and Zhang et al. 2018. Furthermore, the following sentence has been added after Line 2782, "RE-Fe alloys were reported to have greater PFC emissions than other RE metals (Cai et al. 2018; Zhang et al. 2018), consistent with the greater risk of PFC generation expected with the higher temperature and cell voltage operation required. "

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
3273	3	4	2824	2824	The EF(CF4) for Re-iron alloys is shown as 146.1 g/t. However, for the two papers cited, the value reported were 106 and 109.4. Is there a citation missing or an error? Also, the EF (CF4) is shown as 35.8 but the average of the 4 values cited (26.9, 26.66, 36.16 and 33.96) is 30.9. If a method other than a straight average of the measured EFs was used, the authors should specify it.	United States of America	Accepted	Footnotes a in Table 4.28 have been updated, noting that the (Zhang et al 2018) value of 106 g-CF4/t-metal for Dy-Fe production was divided by 57.97% gas collection efficiency (% process gases sampled vs. lost, from Cai et al. 2018 study). This is a straight average. Similarly Footnotes b in Table 4.28 have been elaborated, noting that the 26.9 g-CF4/t-metal for Nd metal (Zhang et al. 2018) was corrected by dividing by the same 57.97% gas collection effiency from Cai et al. 2018 study. This was a straight average.
3275	3	4	2824	2824	Footnote a: Are the two industrial measurements from a single plant? Or two different plants? Both cited papers characterize the data as from a single cell from Qiangdong. Consider revising footnote to specify number of locations and not just number of measurements.	United States of America	Accepted	Footnote a in Table 4.28 has been updated, clarifying that this is 2 industrial measurements from the same facility for the default EF for Dy-Fe production.
63	3	6			The GL needs to give more concentration on the ghg emissions from electronic industries because of its high dangerous toxicity compared to other anthropogenic emissions.	Egypt	Rejected	IPCC Guidance on GHG Inventories is intended to focus on national GHG emissions, not other types of emissions or impacts (in-door or toxic concentrations).
1045	3	6	678	892	Emission estimation methods for semiconductor, LCD and photovoltaics manufacturing given in the guidelines are complex and not always straightforward for Tiers 2 and 3. It is for example indicated that in method 2a it is not necessary to know substrate sizes (e.g. lines 141-142, 680-684). However in order to calculate eq. 6.10 with the default values in Table 6.4, the wafer sizes have to be known. The guidelines for Tier 2a should clearly point out that it is also good practice to calculate emissions without taken into account the emission control systems if those are not in place or would require too heavy reporting burden for facilities (e.g. eq. 6.12 requires too detailed (min/year) information on operating times).		Accepted	Adding Tier 2a values for gamma. We will note that it is good practice to account for abatement but it is acceptable to report unabated emissions.
1047	3	6	1160	1162	Please replace phrase "good practice" with word "advisable" in this sentence. This requirement is too strict for example for small research institutes in which production capacity is low and new gases or process types are just tested. It is not feasible to collect data on Tier 3 level from these facilities supposing that the data is even available if the emissions from this source are insignificant compared to country's total GHG emissions. Also please check other parts of this chapter referring to this "accounts for (less than) 1%".	Finland	Accepted with modification	The term "good practice" was maintained; however, authors agree that an additional threshold is needed and have modified text
1049	3	6	1168	1173	The statement that county-specific default emission factors are less desired is confusing. Country-specific emission factors can be used if their use is justified. On the other hand, default emission factors given in guidelines should not only be country-specific. Please edit sentences.	Finland	Accepted	Language revised.
1293	3	6	757	757	The units for "EABi,CF4" and "Ci" are not given (may be prescribed in "kg"). They should be provided.	India	Accepted	Added units (kg)

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
1297	3	6	1013	1013	Usage of parameter "k" not reflected in Equation 6.15 in line no. 994.	India	Accepted	Deleted k
3277	3	6	1	2107	The electronics and RAC chapters include several fluorinated compounds that are not currently addressed in Chapter 1 (Introduction) of Volume 3. Chapter 1 should be updated to remain consistent with Chapters 6 and 8 and especially with Volume 1, Chapter 8, section 8.2.2 ("Gases Included"), II. 108-145, and with the updated Reporting Tables.	United States of America	Accepted	Chapter 1 has been updated to include additional GHGs.
3279	3	6	119	2404	The electronics chapter is relatively long and complex. Therefore, the guidance needs to be focused and streamlined to make it more usable by removing repetition (particularly within and between the Introduction and Choice of Methods sections), by reorganizing some discussions, and by adding tables to summarize information that is currently sprinkled throughout the text.	United States of America	Accepted	Chapter was clarified and streamlined.
3281	3	6	133	158	This list should be edited to remove redundancey and clarify which subsectors have had EFs updated (SC, LCD), which have not (PV), and which are entirely new (MEMS). Because a similar list of changes appears later in the Introduction, it probably makes sense to move this bulleted list (with the edits suggested) to the Mapping Tables.	United States of America	Accepted	This list was edited and moved to the mapping tables.
3283	3	6	138	138	Clarify that apportioning may also be required between wafer sizes.	United States of America	Accepted	Clarified in list; entire list was moved to the mapping tables
3285	3	6	154	154	Provide additional detail regarding updates to guidance regarding fluorinated liquids (e.g., mention new EFS for packaging, testing, and soldering).	United States of America	Accepted	Additional detail was added to the list under "Tier 1 method".
3287	3	6	163	163	To increase readability, strongly recommend breaking the Introduction into two smaller sections called something like "Overview of Emissions and Their Sources" and "Summary of Refinements," and reorganizing as necessary to remain consistent with these titles.	United States of America	Accepted	Subheadings were added as suggested
3289	3	6	174	174	Should note that fluorinated liquids are sometimes used to clean substrate surfaces, e.g., for MEMS.	United States of America	Accepted	Added substrate surface cleaning for MEMs to list of fluorinated liquid uses.
3291	3	6	175	175	Correct to indicate that fluorinated liquids are no longer believed to be used to clean TFT display panels during manufacturing. (They were used before 2010)	United States of America	Accepted	Added "before 2010" and clarification that they are no longer used
3293	3	6	175	176	Delete "Inventory compilers should also account for" since this section is intended as background rather than guidance. Similar language should also be deleted at 182.	United States of America	Accepted	Removed "inventory compiles should aslo account for" from setences
3295	3	6	177	177	Note that "dry removal of photoresist" is an additional "other" N2O using process.	United States of America	Accepted	"Other" N2O using processes examples were expanded to included dry removal of photoresist
3297	3	6	183	183	"light emitting devices" should be "light emitting diodes"	United States of America	Accepted	Changed
3299	3	6	193	211	This is a rather long paragraph and currently, the sentences regarding the sources of emissions run together. It should be revised to more clearly call out the different emissions sources.	United States of America	Accepted	Paragraph edited for clarity
3301	3	6	207	210	Delete sentence beginning "However, if the emissions control system's OEM." This level of detail is too high for an introduction.	United States of America	Accepted	Deleted sentence

3449	3	6	1268	1349	The preliminary estimate and subsequent methods used to estimate	Country	Accepted	Changes made.
3443			1200	1343	emissions from untested stacks raise a number of challenging issues.		Accepted	Changes made.
					First, the preliminary estimate permits the use of unweighted tool counts			
					to apportion gas usage to various stack systems (II. 1282-84). No			
					distinction is made between etching and TFD equipment. Since the			
					preliminary estimate is the source of the factor (theta) used to scale up			
					the EFs to account for untested stacks, errors here are a significant issue.			
					Second, the equations for the gas-specific emission factors (6.26 and			
					6.27) assume that (1) the uptime of abatement equipment for the facility			
					is the same as the uptime of abatement equipment for the tested stacks,			
					and (2) the fraction of gas abated (ai,f) for the facility is the same as the			
					fraction of gas abated for the tested stacks. Both assumptions appear			
					questionable. Consider whether it may actually be simpler to require			
					testing of all stacks initially, and then to permit less frequent testing of			
					stacks that are identified as low-emitting through the initial test. This			
					would eliminate the theta factor from Equations 6.26 and 6.27.			
					would committee the theta latter wom Equations size and size

1057	3	8	391	393	Please remove the text ", but, by analogy with plasma-based processes used in the electronics industry, FC emissions resulting from the use of input gases such as CF4, C2F6, CHF3, SF6, and other fluorine-containing molecules in plasma processes may be significant." There is no actual indication of the potential significance of the emissions level from this source and therefore no speculation on the possible significance should be presented in the guidelines.	Country	Rejected	It is true that there are no available data about the textile fluorocarbons coating emissions in the atmosphere, however, treatment of both textiles and electronics with different kinds of plasma gas is a well-studied subject. There is no doubt from the scientific point of view that these process can have an incomplete use of the input gases or low emission of residual fluorocarbon monomers. The problem is the lack of information about the extent of this emissions and their relevance as GHG gases. However, considering that the world market of textile finishing repellent agents has been estimated to be 24.5 million tons in 2015, there is no doubt that even very small FC emissions released from these process could represent a significant new source, due to the large volume of substrates treated. The authors recognise the need for clarification in order to avoid misunderstandings by reediting the sentence as follows: "The extent to which plasma-based textile treatment processes have penetrated volume production is unclear, but, by analogy with plasma-based processes used in the electronics industry, and considering that many FC molecules are particularly stable and difficult to disassociate, the utilization efficiency of the input gas is likely to be limited, and FC emissions resulting from the incomplete use of input gases such as CF4, C2F6, CHF3, SF6, and other fluorine-containing molecules in plasma processes may be significant"
						Finland		
1299	3	Annex 1	28	28	In Column D (CO2 emissions); Equation should be divided by 1000 to arrive at Gigagrams from tonnes. Or otherwise, the unit of column D should be changed to "tonnes"	la dia	Accepted	
1301	2	Annex 1	30	30	Similar comment as above for column E	India India	Accepted	
1303	3	Annex 1	32	32	Similar comment as above for column D	India	Accepted	
1305	3	Annex 1	86	86	Under Column E: it is unclear how kg value is being divided by 10^9 (instead of 10^6) to arrive at Gg value.	India	Accepted	Units for the emission coefficients C1 has been adjusted to "g CF4/s-tonne Al". This was an error in units. When divided by 10^9, this now correctly gives emissions in Gg CF4 units. The units have been corrected in both Annex 1, as well as in the Final Draft (variables for Equations 4.27b and 4.27f).
1307	3	Annex 1	89	89	Similar comment as above for column E	India	Accepted	Units for the emission coefficients C3 has been adjusted to "g C2F6/s-tonne Al". This was an error in units. When divided by 10^9, this now correctly gives emissions in Gg C2F6 units. The units have been corrected in both Annex 1, as well as in the Final Draft (variables for Equations 4.27b and 4.27f).
1383	3	Annex 5	17	17	Annex 5. The line reads: "CHAPTER 3". It would enhance the understanding if the line read: "CHAPTER 3 CHEMICAL INDUSTRY". This is relevant for all chapter headings in Annex 5.	Sweden	Noted	The format of the Mapping tables is standardised across all Volumes; the text in Annex 5 is consistent with the approach in other Volumes.

3739	4	1	467	468	Table 1.2: Wetland (chapter 7). In this section only emissions of CO2 and non-CO2 gases are expected to be estimated. However, flooded land remaining flooded land, such as hydroelectric reservoirs, can have a potential to fix significant amount of CO2. Does this mean net emissions including removals?	Norway	Noted	Removals of CO2 due to activty of biota (e.g. bacteria, macroinvertebrates, plants, fish, and other aquatic species), but these removals reflect short-term carbon cycling by the aquatic biota, and are not addressed in this guidance. There may also be storage of C in reservoirs that is transported from upland systems. This C is addressed as a loss in the upland systems, but estimating the amount of C that it is transferred to the reservoir is challenging as discussed in Box 7.1. Compiler may estimate these transfers, but this requires a higher tier method.
					Table 1.2: Cattlements (chanter ()) Please consider if possible PCP as a			
3741	4	1	467	468	Table 1.2: Settlements (chapter 9). Please consider if possible BGB as a potential carbon pool in the subcategories of both Settlements Remaining Settlements (SS) and Land converted to Settlements (LS) since urban green space can act as a carbon sink (Strohbach et al 2012).	Norway	Noted	Belowground biomass may be estimated and reported at Tier 2 or 3 as discussed in Chapters 2 and 8.
3743	4	1	467	468	Table 1.2: Other land (chapter 9). Below ground biomass might be a potential carbon pool in the subcategories of both Other land Remaining other (OO) and Land converted to other land (LO).	Norway	Noted	Changes in C stocks are only estimated for Land Converted to Other Land, but not for Other Land Remaining Other Land because these areas are typically exposed rock, glaciers or other similar areas without vegetation. Regardless, changed in belowground biomass may be estimated for Land Converted to Other Land using higher tier methods as discussed in the generic methods for Chapter 2 and additional guidance in Chapter 9.
3745	4	1	469	470	Table 1.2: Managed soils (Chapter 11). Manged soils, depending on the type of management and environmental conditions, can be both sources of emissions and potential greenhouse gas mitigation, e.g., no-tillage, application of biochar, animal manure and crop residues. Please consider both cases in the estimation of net carbon pools.	Norway	Noted	The removals are addessed in the soil C methods provided in Chapter 2 and further guidance in each of the land use specific chapters for forest land, cropland, grassland, wetlands, settlements and other lands.
69	4	2	495	542	The use of allometric models for biomass estimation is written in good details, meanwhile, it's still not easy to identify the best model to be applied to assure that the model accuracy is equal or higher than available default factors of Biomass Emission Factors (BEFs), selection of the best model may steel in need for more improvements	Egypt	Noted	As stated lines 495-501 "The accuracy of the models may be lower than e.g. available default factors or Biomass Emission Factors (BEFs), so it is good practice to choose the method with the higher accuracy". Guidance is then provided on how to select the best allometric model/s, in particular lines 513 - 531.
105	4	2	624	625	We think, and the text confirms it, that the use of biomass density maps from remote data can only be accurate to estimate aboveground biomass. Therefore, we ask for the inclusion of ABOVEGROUND in the title of section B. It would read "Using ABOVEGROUND biomass density maps constructed from remotely sensed data for biomass estimation"	Spain	Accepted	We added "aboveground" in the title

					suggest its deletion, together with the explicative text below, that we also		Accepted with	because each year only 1/n panels are measured (Röhling et al.
123	4	2	2511	2512	find misleading and confusing.	Spain	Modification	2016)
125		2	2564	25.00	In this paragraph there is a clear difference between salvage logging and other management activites after natural disturbances, the difference being that salvage logging can be considered harvested wood products later, therefore, accounted twice if it is not explicitly identified in natural disturbances reporting. Deforestation after NDs also needs a different treatment, as emissions will need to be considered in the land conversion lines in reporting tables. But for the other management activities (soil protection, pests protection, seeding, etc.) there is no need to disaggregate emissions and removals. We propose to replace the paragraph by "if a country choses to disaggregate ND emissions and removals, the it is good practice to disaggregate as anthrpogenic emissions in NDs those resulting from salvage logging and defforestation, if applicable."	Spain	Rejected	The fact that emissions from human activities are considered anthropogenic is the foundation of the IPCC GL. We therefore reject the notion that some activities, e.g. those following a natural disturbance, could be considered non-anthropogenic. Note also that if a country chose to declare such emissions to be natural (e.g. emissions from site rehabilitation after wildfire) then the subsequent removals would also have to be considered natural, as already outlined in the text.
123	4		2304	2306	п аррисане.	эран	Rejected	considered flatural, as already outlined in the text.
127			2016	2620	CH4 and N2O can be subject to subsequent removals in terms of CO2 equivalent, so the balance can be achieved to the total emissions excluded on a CO2eq. basis. This should be reflected in the text. We suggest replacing from "non-CO2 emissions are not taken up by vegetation" to the end of the paragraph by "non-CO2 emissions will take longer to be taken up by vegetation in terms of CO2eq, therefore, there is expectatins that these emissions are to be balanced, but conversion factors to CO2eq (i.e., GWPs) need to be taken into account. "This is how European countries calculate their balance for natural disturbances. Not only CO2 is taken into account, but also the N2O and CH4 emissions in	Caria	Accepted with	The CH4 and N2O emisisons decay to zero in atmosphere because of bio-chemico-physical process that are not included in the NGHGI. Consequently, their balancing to zero cannot and need not to be tracked within the NGHGI. Although the original text has been revised with the following change to make it more clear: " there is no expectation that these emissions will be balanced by removals because the biological, chemical and physical processes that result in the complete decay of CH4 and N2O in the atmosphere are not
127	4		2616	2620	CO2eq.	Spain	Modification Noted	captured
					Second diamond box after start: Needs to distinguish between Land use and management because a country may have reference C-stocks for different land use but not for management (which is more disaggregated). In fact, it is unlikely that many country will have representative reference stocks for different managements at national level, hence Box 2 would not be used.		Inoted	Reference stock refers to stock present non-degraded, unimproved lands under native vegetation (in essence under no management). The practices applied to managed soils have no impact on the reference stock.
163	4	2	1086	1087		France		
					Third diamond box after start : Needs data on animal manure too		Accepted with Modification	Given the decision to move the Tier 2 Steady State Modelling approach to the Croplands chapter, it should no longer appear in the generic discussion pertaining to soils. The third diamond has beeen removed from the figure.
165	4	2	1086	1087		France

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
175	4	2	2109		In practice, data for model calibration (and for calibration of any relevant process represented in the model) is often scarce and it is unlikely that data for both calibration and evaluation will be available. An alternative is to use the data only for quantifying and modeling the bias and precision of the model (see Box 2.2H) and include this statistical modeling in the Tier 3 approach (more details in the Step 6, I.2257, and 7, I.2338, of the Tier 3 approach).	France	Accepted with Modification	Even in the case where an empirical model is developed to quantify uncertainty in the model, these data must be independent from the data that are used to develop and parameterize the model. Otherwise, the uncertainties are based on how well the model is calibated to the sites used in the parameterization, and not how well the model predicts emissions across the the spatio-temporal domain of the inventory. Nonetheless, based on other comments the good practice text has been modified to be less specific.
177	4	2	2111	2111	"Calibration data should, where possible, match the quality and scale of data sets used in the GHG inventory." the term "scale" is unclear. Does it mean here "spatial resolution" or "spatial perimeter"? Please consider rephrasing this term.	France	Accepted with Modification	It is good practice for the calibration data to be representative of the environmental conditions occurring within the country. In practice, this does not mean that all environmental conditions are covered, but that the original calibration data includes a range of the conditions existing in the country that is representative of national circumstances. A sentence has been added that the variance is estimated based on the two stage sample of the NRI and a reference is given more information. It is beyond scope of this guidance to
179	4	,	2332	າວວາ	Please detail the method (as it is done for the other steps of the variance estimation)	France	Accepted with Modification	provide the full derivation of the two-stage sample variance estimation.
283	4	2	1020	1024	This introductory paragraph in grey should introduce the term used in equation 2.24 for biochar amendments added to mineral soils	France	Accepted with Modification	Action: The Δ BCmineral equations from Equation 2.24 were moved to Equation 2.25 to make it more clear that biochar has been included just in the mineral soil section. A sentence for Δ BCmineral has been included in the introductory paragraph for Mineral soils.
					Assuming that soil organic C stock change during the transition to a new equilibrium SOC occurs in a linear fashion over a period of 20 years is an approximation. Numerous data point to non linear (e.g. exponential) changes with SOC being lost more rapidly in initial years after a change in management leading to reduced SOC stock after 20 years. E.g. Soussana et al., 2004. Carbon cycling and sequestration opportunities in temperate grasslands. Soil use and management.		Noted	This would add too much complexity for a Tier 1 method. This issue was already identified in the text and the fact that the linear approach is an approximation was pointed out. The non linear dynamics can be addressed at higher tiers.
285	4	2	1074	1075		France		
287	A	2	1098	1102	By contrast to the specific case of biochar addition to mineral soils, this update does not provide improved guidance on stock change factors for inputs of organic matter to mineral soils. Improved guidance on organic amendments, their organic carbon contents and the long-term fate of the added carbon, depending on the nature of the organic amendment (e.g. manures, slurries, composts, etc) would however be useful.	France	Noted	A literature review was conducted but there was not sufficient data to update the input factors for other organic amendments.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
291	4	2	454		Most allometric equations (especially in Globallometry) are used to calculate wood volumes. To switch to biomass, it is necessary to use wood densities (Réjou-Méchain et al. 2017, https://doi.org/10.1111/2041-210X.12753), a step to which particular attention must be paid, particularly to reduce uncertainties (Picard et al. 2015, https://doi.org/10.1007/s10310-015-0510-5). Global databases exist on this subject, including Zanne et al. 2009's Global Wood Density Database (https://doi.org/10.5061/dryad.234/1) - see also Flores and Coomes 2010 (https://doi.org/10.1111/j.2041-210X.2010.00068.x). This is a different issue from biomass density maps (section 2.3.1.1.3.B) so we suggest that additional explanations be provided on aspects related to the use of wood densities in the section	France	Noted Noted	The importance of wood density is included in the guidance in Chapter 2.3.1.1. Refer also to section "The use of allometric models" lines 495 -542, where different properties (volume, mass, C stocks) are referred to as possible results of the application of allometric equations. We are not endorsing biochar amendments as a best management practice. The Special Report and other related documents are the proper place to discuss merits and problems with biochar amendments. However, it is an anthropogenic activity that impacts soil C stocks, and accordingly addressed in this report to estimate anthropogenic greenhouse gas emissions and removals. Incorporation of impacts of biochar type and chemical attributes, soil type, climate and interactions on persistence would move the method to Tier 2 or 3.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
301	4	2	2830	2832	Land management after natural disturbances includes forest salvaging, but also many other activities, such as site rehabilitation, water erosion prevention, removal of dead shrubs and dead non-commercial trees, replanting or seeding, etc. This paragraph suggests that all management is to be considered anthropogenic, but salvaging and deforestation are different from other types of management and should not be treated equally (that was the consensus in KP accounting rules). The paragraph seems to suggest that the best course of action is to "do nothing" on burnt areas. This may well be the case in some remote areas, but it is certainly not in densely populated areas and/or with actively managed forests and landscapes. The difference mostly lies in the fact the salvaging will avoid emissions in other forestlands. Treating salvaging as non-anthropogenic emissions would lead to an imbalance in emissions reporting in forest land, i.e. the "extra" removals in non-affected lands would count, but the "extra" emissions in burnt areas wouldn't. Deforestation does not guarantee any future removals and is by nature a human induced decision and so it is consensual that it should be treated as anthropogenic. On the other hand, other types of management aim at speeding up post-fire recovery and the quality of the future forest. We suggest these nuances should be inserted into the text.	France	Rejected	This paragraph only calls for documentation (and thus transparency) of the methods and assumptions made by a country. This text makes none of the assupmtions specified by the reviewer. In particular, there is no suggestion in the text in lines 2830 to 2832 about the course of action to take, or that salvage should be treated as non-anthropogenic emission. Earlier in the text it was stated that management activities such as salvage logging or site rehabilitation of areas affected by natural disturbances that cause emissions that are anthropogenic and that subsequent removals on ND lands can be used to balance these emissions.
303	A	2	2616	2620	The balance of non-CO2 gases emitted through natural disturbances on managed lands cannot be reached on a gas-by-gas basis but can be considered on a CO2eq basis and/or a lower anthropogenicity in the subsequent removals. According to the first option, GHG emissions, including CH4 and N2O emissions, could be balanced by future CO2 removals, leading to an higher stock than the pre disturbed levels. According to the 2nd option, using the of distinction between anthropogenic and non-anthropogenic, the additional CO2 balance needed to offset non-CO2 emissions can be made by reducing the anthropogenicity of subsequent removals. We suggest the following editorial suggestions: "In addition to CO2 emissions, natural disturbances may cause non-CO2 emissions, e.g. wildfires cause N2O and CH4 emissions. While CO2 emissions are assumed to average out across time because of vegetation regrowth after disturbance, non-CO2 emissions are not taken up by vegetation and therefore balancing these emissions by removals can only be made if there is a reasonable possibility for future forest C Stocks to exceed the pre-disturbance levels by an amount equivalent to the non-CO2 gas emissions and/or by reducing the share of removals considered anthropogenic by a level equivalent to the non-CO2 gas emissions."	France	Accepted with	The CH4 and N2O emisisons decay to zero in atmosphere because of bio-chemico-physical process that are not included in the NGHGI. Consequently, their balancing to zero cannot and need not to be tracked within the NGHGI. Although the original text has been revised with the following change to make it more clear: " there is no expectation that these emissions will be balanced by removals because the biological, chemical and physical processes that result in the complete decay of CH4 and N2O in the atmosphere are not captured

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
					The equation to take into account biochar effect is strange because it also		Accepted	It has now been decided that emissions of non-CO2 GHGs (e.g.

911	4	2	983		The format of table 2.2 should be revised. The variation of the default value shown in the table is too large to represent the data ability.	Republic of Korea	Rejected	The format of table 2.2 was kept from the 2006 GL, but the content was revised, based on an substantial literature review. The variation reflects the literature considered.
					As the soil carbon maps presented as an activity data for this section are		Accepted	References removed
04.2			4546		made in a global scale, it may be appropriate to use Tier 1 level rather	Danublia of Kanaa		
913	4		1516	1517	than Tier 3.	Republic of Korea		
971	4	2	453		An Allometric Model, which is of great limitation in application, is only suitable for small-scale projects or stand level, but not for large scale and national-level greenhouse gas inventories. Due to the complexity of its application, this can not be regarded as a "good practice". Moreover, this section, which gives only a conceptual description of "Allometric Models", does not indicate how to use it in inventory preparation. So it is suggested to give instructions in this connection. If they are not available, it is suggested to delete the mention of this model directly.	China	Rejected	The concerns are all addressed in the guidance. Allometric models are often used at national scales. Guidance is provided at the level required for inventory compilers to undestand in which context they can be used and not given concrete models or instructions how to construct them. There is already a considerable body of work available in the literature on the application of allometric models that can be consulted. As allometric models are in common use in inventories in particular when tier 2 is used, some general guidance for inventory compilers was considered necessary.
973	4	2	818		Considering the decomposition of dead wood, it is not appropriate to set its Carbon Fraction (CF) at 0.5. So it is suggested that its CF be revised to 0.37 the same as Litter.	China	Rejected	Thank you for the comment, we have clarified that this value is for temperate tree species. Unfortunately there is very little data on this topic so the values given here are default values, to be used if no more detailed information is available. The transition from wood to litter is gradual, as is the change in CF, and setting the CF of dead wood equal to that of litter would be incorrect.
1073	4		1216		The equation 2.26A (New guidance) for estimation of annual soil C stock changes associated with biochar amendments include terms "global warming potential of methane and nitrous oxide produced during pyrolysis in unit of CO2 eq". The meaning of these terms in equation is not properly explained but indicate that CH4 and N2O emissions formed during the pyrolysis process to produce biochar would be subtracted from the C stock changes when biochar is used as a soil amendment. This does not seem consistent with general prinicples applied in IPCC Gls to estimated emissions of CO2, CH4 and N2O separately, and also to report emissions where they occur. It could also lead to double counting of emissions when these emissions would be reported in the energy sector (see Vol. 2, chapter 4). Please clarify the meaning and revise the equation, as appropriate.	Finland	Accepted	It has now been decided that emissions of non-CO2 GHGs (e.g. CH4 and N2O) during the heating process used to produce biochar will be recorded in the Energy sector of national inventories (see Volume 2, Chapter 4, Table 4.3.2.1 for values associated with charcoal production).
10/3			1210	1234				
1075	4	2	2348		Comparison of model-derived inventory estimates with the estimates of the previous submissions is not verification with independent data (as caption says) but normal QA/QC, please remove - unless different model was used in the previous submission but that would need more guidance to be clear to inventory compilers.	Finland	Rejected	The text does not suggest comparisons with previous inventory estimates as a verification process. Rather we note that is it possible to use other data sources, such as harvest statistics, to help verify the mdoel results, while noting the potential issues when doing so.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
		·			Is the section on interannual variability in line with the Terms of Reference? The focus is on ND that are not mentioned in the TOR but very little guidance is given for ND (best suitable for an appendix) and		Accepted with	Text in Chapter 1 has been revised to further clarify the purpose of Chapter 2.6 in line with the 2019 Refinement ToR. Nevertheles, authors disagree with the reviewer's suggestion that is "best suitable for an appendix" and the assessment that "practically no methodological guidance for interannual variability" was given. IPCC guidelines sets a strong precedent for enabling countries to apply their own definitions and methods within the framework of good practice and this section continues this approach. This section provides inventory compilers with the framework for developing country specific estimates following IPCC guidance, rather than dictating to countries how they
1077	4	2	2382	2832	practically no methodological guidance for interannual variability per se.	Finland	Modification	must implement their inventory.
1079	4	2	2454	2832	Please place the draft guidance on ND to an appendix as there are not enough guidance given, no scientific method i.e. no mention what would Tier 1 be (or assumptions of it to be zero) and in addition, the current guidance appears to be a mixture of no guidance and some rules that can be interpreted to be more accounting rules than IPCC guidance (examples: proportion with which the subsequent removals should be allocated between ND and anthropogenic activity, taking into account current removals occuring on sites of the past natural disturbances (pre-1990) to balance out current ND losses). There is no guidance for taking into account the carbon storage in soil as well as in DOM pools in case of natural disturbances which would be needed if this ND guidance were to remain in Chapter text and not placed in an appendix.	Finland	Rejected	The method proposed is not an additional methodological tier, to be applied. It is just a refinement that countries that wish to do so can apply to refine the managed land proxy. Its application does not impact any of the methodological guidance provided by IPCC on how to estimate GHG emissions and removals from carbon pools (including soils) in land use categories.
1081	4	2	2454	2832	Please remove frequent references to countries in the text, i.e. the guidance should not be based on approaches or conditions of individual countries but should consist of more generic guidance approved by the experts and supported by literature.	Finland	Rejected	The term countries has beed used consistently throughout all 2019 Refinement to refer to countries collectively (generically) rather than individually. Country examples are given in boxes with the caveat that boxes are "for information only and neither adds guidance nor overrules guidance provided". In addition, according to "instruction to Authors" within the 2019 Refinement TOR "Lead authors must consider all recent scientific developments and national methods used by countries in their inventories".
1083	4	2	2407	2408	IPCC Expert Meeting Report would be the correct title, as it is not a question of reviewed report compiled by experts but a meeting report as stated in the list of references as well and given as a citing recommendation in the report in question. Please correct.	Finland	Accepted	Text revised as suggested

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
					Comment: We welcome the inclusion of guidance on calculation of biochar C, and largely agree with the approach. Ideally pyrolysis temperature should not be the distinguishing factor for biochar persistence but rather the elemental ratio H:Corg (at least to some extent long residence time can substitute for lower temperature, in terms of degree of carbonisation). We acknowledge the need for the Tier 1 method to be simple to apply, but are not convinced that it is easier to obtain data on kiln temperature than chemical analysis of biochar. Also, the considerably higher stability assumed for higher temperature char does not have strong basis, and may encourage gasification instead of slow pyrolysis, with net reduction in biochar produced, and biochar with lower agronomic value. Also, as noted at line 1053, 1000 years is overly conservative as a "permanence period". 100 years would be consistent with permanence requirements for other sequestration measures.		Accepted with Modification	The calculation of Fperm has been changed from a linear regression to heating temperature categories to account for the known non-linearity between pyrolysis temperature and biochar C persistence. Justification for this change has been added to Annex 2A.2. The Tier 1 methodology was based in temperature rather than biochar properties (such as the mentioned H/Corg or O/C ratios) to facilite accounting in the framework of a Tier 1 method. H, O, and C analyses using Dumas combustion requires specialized equipment that is not available in many countries. In addition, costs for analyses will also constrain the applicability of the method. Mandating the use of elemental ratios will reduce the ability to account for biochar additon to mineral soils. Countries with the ability to measure biochar properties are encouraged to use the recommended Tier 2 and 3 methods; appropriate reference was added to the method and appendix. The text in Annex 2A.2 defining how Fperm was calculated was revised. The revised values of Fperm have been added to Table 2.3B. Text has also been added to Annex 2A.2 defining the potential use of O/C and H/C ratios in higher Tier methods.
1155	4	2	1215			Australia		
1157	4	2	1333		Recommend noting the possibility of measuring SOC stock change by equivalent mass rather than depth, as this requires consideration of C stock below 30cm depth.	Australia	Accepted	The following sentence has been added: For developing a Tier 2 method it would also be possible to define reference SOC stocks and SOC stock change factors using an equivalent mass approach (see Box 2.2B) rather than an approach based on a fixed depth.
					Recommend clarification: Three fractions are mentioned in line 1554: particulate, humus and resistant. It is not clear whether "decomposable and resistant plant materials" are included in one of these fractions. Derivation of decomposition rates of resistant and humus fractions is mentioned, but not for particulate fraction. Line 1585 introduces the term inert fraction which is not mentioned previously - is it different from resistant?		Accepted with Modification	In point 2) the relationship between the measureable fractions of SOC (particulate, humus and resistant) to the respective model pools (resistant plant material, humus and inert) is identified. The inert fraction is clearly identified. References are provided that go into detail about this relationship and what the fractions and pools represent. In point 5) the calibration of the model pools is discussed using the terms applied to the model pools. However, in referring to the resistant plant material pool, it was only labelled as resistant which could cause some confusion.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
								Text in Chapter 1 has been revised to further clarify the
								purpose of Chapter 2.6 in line with the 2019 Refinement ToR
								and the outcomes of the May 2009 expert meeting on the MLP.
								Nevertheles, authors disagree with the reviewer's
								interpretation of the Expert Meeting outcome based on two
								quotes from the report:
								1) "While the meeting agreed that annual emission inventories
								should estimate the actual emissions in the inventory year, it
								was also noted that there is a need to be able to identify the
								impact of mitigation and management efforts even where
					This introductory section should clarify the purpose of Ch2.6 by making			these are obscured by inter-annual variations in greenhouse gas fluxes for example by the impacts of natural processes (e.g.
					explicit reference to the ToR and the outcome of the May 2009 expert			wildfire) or indirect human-induced processes (e.g. climate
					meeting on the Managed Land Proxy. In particular, this meeting agreed			change impacts)"; and
					that annual emission inventories should estimate the actual emissions in			change impaces/ , and
					the inventory year and that the aim of emission inventories is not to try to			2) "The meeting hoped that further work by the scientific
					remove or reduce the impact of inter-annual variations (see conclusion 5		Accepted with	community will result in more mature approaches which can be
1461	4	2	2381	2418	in the expert meeting report).	EU	Modification	assessed at a later date."
								Text has been revised to delete the last sentence of the
								paragraph in line with the assessment that " it is impossible
								by definition that existing inventories are following this
								guidance".
								Nevertheless, authors disagree with the assessment of the
								reviewer that "Examples of the existing methods for separation
								of natural and anthropogenic effects in inventories should not
								be included in this guidance".
								Examples are given in boxes with the caveat that boxes are "for
								information only and neither adds guidance nor overrules
					Examples of the existing methods for separation of natural and			guidance provided".
					anthropogenic effects in inventories should not be included in this			
					guidance. Section 2.6 provides new material as far as inventory guidance			In addition, according to "instruction to Authors" within the
					is concerned. Therefore, it is impossible by definition that existing		A	2019 Refinement ToR "Lead authors must consider all recent
1465	4	,	2408	2400	inventories are following this guidance. The last sentence of the paragraph should therefore be deleted.	EU	Accepted with Modification	scientific developments and national methods used by countries in their inventories".
1403	4		2400	2409	paragraph should therefore be deleted.		iviounication	countries in their inventories .
					The terminology here is different from that of the chapter introduction.			
					This is confusing and needs to the corrected. While the chapter			
					introduction (lines 2398-2418) refers to disaggregation of MLP emissions,			
					these lines refer to refined approximation of the anthropogenic			
					component of emission & removals. We recommend that the terminology			
					such as refining approximation and second order approximation be			Text has been revised to removal references to "refined
					removed and the paragraph re-phrased using the term disaggregation,		Accepted with	estimates" but the terminology "second order approximation"
1467	4	2	2446	2453	which should be consistent throughout the chapter.	EU	Modification	(which is achieved through disaggregation) is maintained.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
1469	4	2	2454	2502	This subsection describes a mixture of natural and anthropogenic phenomena, and discusses the relationship between them. Several of the references to Natural disturbances (including the title) are therefore inaccurate and should be changed. We therefore recommend the following: • This paragraph should make clear that effects can have a range of natural and anthropogenic influences. Anthropogenic factors can contribute to effects of natural origin and vice versa. • In lines 2468-2492 (on definition of natural disturbances) it should be made clear that the purpose of greenhouse gas inventories is to estimate and report the actual emissions in the inventory year, without removing the impact of interannual variations. The methodology supplied in this chapter for disaggregation of emissions and removlas into components on the basis of variability of disturbances is made available to countries who wish to use it for other reporting purposes (such as transparency of commitments).	EU	Rejected	The text referred to by the reviewer focusses on natural disturbances as one of the factors that contributes to the IAV of estimated and reported emissions. Thus the focus on natural disturbances is appropriate. Contrary to the statement by the reviewer, the purpose of the GHG inventory is to estimate and report the anthropogenic emissions and removals within the managed lands. It is recognised by the IPCC that not all emissions and removals within the managed land are of anthropogenic origin, and the IPCC has therefore called on the scientific community to advance the science of estimating anthropogenic E/R within the MLP Proxy. The methods outlined here and the numerical examples provided in this report can increase the transparency of reported GHG E/R.
1471	4	2	2536	2541	This paragraph should clarify that applying the Managed Land Proxy (which is described as Good Practice) involves including all estimated emissions and removals occurring on managed land during the inventory period in the reported total emissions and removals. The second sentence should either specify that the methodology for 'further disaggregation' provided in this subsection may be used for purposes other than reporting of greenhouse gas inventories, or the words "from the total emissions and removals using MLP should be deleted.	EU	Accepted with	Text has been revised to further clarify that "It is good practice for countries to apply the Managed Land Proxy (MLP) and estimate and report all emissions and removals that occur on managed lands"
1473		2	2577	7592	This paragraph is a description of accounting which should be removed.	EU	Rejected	The paragraph is just an example of estimation and not a "description of accounting". The text clearly states that the disaggregation of removals to the anthropogenic and natural components is in proportion to the disaggregation of emissions to these two components. This is the guidance required to ensure that the disaggregation of emissions is balanced by the disaggregation of removals to the anthropogenic and natural components. If the goal is to disaggregate emissions then removals also have to be disaggregated.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
					This is the key paragraph but unfortunately it is contradicting in itself:			
					"The natural disturbance component is subtracted from the total estimate			
					of MLP emissions and removals, yielding a refined estimate of the			
					anthropogenic emissions and removals from managed lands." is clearly an			
					accounting step. The following sentence makes clear that this information			Text has been revised to enhance clarity; including replacing
					is provided in addition to reporting total GHG emissions and removals:			the term "refined MLP flux" with "second order approximation
					"This is the "refined MLP flux", i.e. the second order approximation of the			of anthropogenic emissions and removals".
					anthropogenic component of E/R from managed land and is reported in			
					addition to the total MLP emissions and removals."			In addition is important to recall that the paragraph (and the
					The idea of 'subtracting' natural disturbances from the MLP estimate of			table example provided Box 2.2L) clearly indicated that "all
					emissions and removals is not consistent with this methodology's stated			emissions and removals are to be reported" in addition to the
					aim of 'disaggregation'. We recommend that:			other components.
					• the term "refined MLP flux" be renamed. Since this flux is not consistent			
					with the MLP concept, it should have another name to avoid confusion.			Finally, the decision what is to be reported in the CRF tables is

					convergent and are provided as guidance. They either intend to justify			
					that ND can be removed during reporting (example AUS) or they are not			
					clear that the ND provision is applied during accounting (EU-case), which			
					is outside the scope of this chapter.			
					The labelling of the boxes as both "new guidance" and "for information			
					only" is also extremely confusing.			
					There appears to be a discrepancy between the methodologies used and			
					the interpretation of the results. E.g., the approach presented in Box 2.21,			
					"natural disturbances" are defined as those "occurring in a year which is			
					an outlier". Therefore, the disaggregation seems to be done on a purely			
					statistical basis (which is a reasonable approach to "inter-annual			
					variability"). However, the resulting two components seem to be attributed to purely natural and purely human-induced causes, despite			
					causality hot having been part of the disaggregation. It is unclear what			
					evidence supports the attribution made. Moreover, even if this			Text has been revised to remove the word "Guidance" from the
					attribution is supported by more detailed evidence for the country			boxes as these are examples of national methods, not

1501	4	2	1725	1745		EU		
					The attention to charcoal application to soil ("biochar") in this chapter is absolultly unbalanced given the current relevance of the technology. In addition there is no single mentioning of the potential negative effects of "biochar" to the environment and human health. Pyrolisis of inappropriate feedstocks can generate severe health effects on humens and other species. Inappropriate application technologies can have ecffects on soil health and water quality. There are still large areas of uncertainty on the systematic application of charcoal on soils that do not allow for an endosrement of the technology as an IPCC methodology. The precautionary principle should apply in this case.		Noted	We are not endorsing this technology, but are providing a method for an anthropogenic practice that impacts C stocks of mineral soils to which biochar has been applied.
1503	4	2	3635	3722		EU		
					The evidence base for the fraction of charcoal amendment that will remain after 1000 years may be partly inconsistent with the definition of "biochar" provided in lines 1045-1056. According to Figure 2A.2-1, a number of sources relate to long-term experiments (decadal to millenial time scales). In the case of long-term experiments, it cannot be established that the source of charcoal amendment excluded pyrolytic organic materials that result from wild fires or open fires, which would not constitute "biochar". In the case of terra preta, it is likely that such sources were used (Cattle et al, 2014). Replacing the term "biochar" with "charcoal amendment" could facilitate consistency. Cattle, J., Singh, B., Kookana, R. S., Boersma, M., Macdonald, L. M., Butler, G., Kimber, S. (2014). Opportunities and constraints for biochar technology in Australian agriculture: looking beyond carbon sequestration. Soil Research, 52(8), 739. https://doi.org/10.1071/sr14112]		Accepted with Modification	The Fperm values in this methodology were calculated using values from only those experiments that utilized isotopically labeled biochars allowing unambiguous attribution of evolved CO2, as shown in (a) of Figure 2A.2-1. The values in (b) are added to provide decadal to millenial observational data; however, due to the fact that these were not isotopically labelled (therefore, not allowing definitive attribution of stock chages to different sources), they were not used to derive Fperm values. For this reason the data shown in (b) cannot be used to calculate actual Fperm values. We note, however, that the value calculated here (0.56) is below the values obtained for studies that met the criteria for inclusion in the derivation of Fpermp values. The term 'char' was added to the description of (b) in text and caption to indicate that these can be naturally accumulating pyrogenic organic matter in addition to purposefully added biochar.

CommentID	Volume	Chanton	Fromline	Toline	Commants	Country	Dospones	Authors' notes
Commentio	volume	Chapter	Fromiine	Toline	Comments	Country	Responses	Authors notes
					The whole section on IAV and natural disturbances is concerning as it presents generic, voluntary guidelines that may be interpreted by each country differently. This is not the purpose of the IPCC guidelines, which should provide the best scientific methodologies for estimating emissions / removals, rather than leaving countries to develop their own definitions. Where is the mandate for this development of a generic approach for disaggregating emissions and removals from natural disturbances? This new set of guidelines is a step backwards from previous guidelines and			Text in Chapter 1 has been revised to further clarify the purpose of Chapter 2.6 in line with the mandate given by the 2019 Refinement ToR. Nevertheless, the authors disagree with the assessment that "this new set of guidelines is a step backwards from previous guidelines and guidance developed by the IPCC for estimating emissions / removals from natural disturbances". The IPCC guidelines sets a strong precedent for enabling countries to apply their own definitions and methods within the framework of good practice and this section continues this approach. This section provides inventory compilers with the
					guidance developed by the IPCC for estimating emissions / removals from			framework for developing country specific estimates following
1561	4	2	2381	2834	natural disturbances. Adoption of this section at this stage would appear very questionable.	Saint Lucia	Accepted with Modification	IPCC guidance, rather than dictating to countries how they must implement their inventory.
1563	4	2	2482	2483	Previously natural disturbances have been confined to only forest land. Could we have some explanation of what natural disturbances are anticipated on these other types of land, and why their inclusion is justified? Is it easy to distinguish natural, non-anthropogenic events on other types of land?	Saint Lucia	Accepted with Modification	Text has been revised to enhance clarity. This chapter specifically refers to General Methodology applicable to Multiple Land Categories. Disturbances listed in the ND definition are not category-specific, they may occur in any of the land categories listed. Further, their occurrence can be identified so far as the land category is not a man made category as e.g. cropland or drained peatlands since in this case it would not be possible to consider any impact not materially influenced by human activities.
1565	4	2	2550	2555	The move to a country-specific defintion of natural disturbances is a shift away from the provisioning of good practice guidelines by the IPCC, towards more generic guidance that different countries can interpret differently. This risks jeopardising the scientific integrity of the IPCC's guidelines. We are concerned that allowing countries to develop their own definitions of natural disturbances will make it very difficult to track what countries are and are not counting as anthropogenic vs. natural, and creates the opportunity for Parties to choose a definition that benefits their accounting balances. This is a serious concern for the integrity of NGHGIs and our ability to collectively track progress in achieving the goals of the Paris Agreement.	Saint Lucia	Accepted with Modification	Text has been revised by stating that definitions of ND need to be "Consistent with the generic definition". This removes flexibility and by making it good practice to document the assumptions, it also increase transparency.
1567			2800	2000	These transparency requirements are very vague and generic. For the new guidance to be a useful addition to previous guidance, much more precise	Caint Lucia	Rejected	Other comments have suggested that such requirements are not necessary. In order to find a "compromise solution" the text represents, in the authors' opinion, an appropriate balance
1567	4	2	2800	2800	requirements should be listed here.	Saint Lucia	Rejected	between transparency and not being perscriptive.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
Commentab	Volume	Спартег	ronnine	Tollie	Biochar: biochar was not mentioned in the report outline, so we are surprised to see it here. We are concerned to see a tier 1 method for biochar as we are not sure that there is sufficient robust scientific evidence to support this methodology. Furthermore, these guidelines do not adequately address the risk of impermanence? According to Fuss et al. 2018, the residence time of biochar varies with temperature and soil type, and may be only a few decades. Additionally, we are concerned that the total lifecycle emissions of biochar would not be adequately captured. It should not be possible to report only the sequestration effect of biochar without also reporting the emissions associated with producing and deploying biochar.	Country	Rejected	Chapters 5 and 6 of Volume 4 include updates to the stock change factors for mineral soils. The refinement was asked to address mineral soil stock change factors. Addition of Biochar C to mineral soil is anthropogenic activity that impacts soil C stocks, and as such the stock change factors needed to be updated to address this impact. The development of these factors required a new calculation to address the influence of biochar on the C stocks of mineral soils given its very different nature and stability against mineralisation in soil. To make it more clear that the inclusion of biochar was to allow a more accurate assessment of C stock changes in mineral soils, biochar has been removed from the general soil equation (Equation 2.24) and the biochar term and its derivation have been added to Equation 2.25 which is specific to mineral soils. Inclusion of a method in Tiers 1 and 2 make less errors than having no method at all. Excluding biochar from the methodology would reduce the accuracy of the method rather than increase it. If a country produces biochar, then the accuracy of its emissions inventory will always be improved by including the best possible estimate of the associated GHG fluxes rather than ignoring them altogether. The reviewer is correct that the mean residence time of biochar varies with the temperature and soil type it is exposed to in the environment. The data in this methodology uses all published data that met the stringent criteria for the period of time and
1569	4	2	1045	1745	The addition of biochar to the 2019 Methodological Supplement is outside the ToR and the Chapter Outline agreed at the Scoping Meeting and as part of the mandate adopted by the IPCC plenary for the 2019 Methodological Supplement. Related to changes in carbon stocks in soils the mandate included only the following three issues 1. Update reference carbon stocks. 2. Develop new Tier 2 method for mineral soils that requires less AD and 3. Elaborate Tier 3 Methodologies with case study examples for soils. Therefore we request to delete the related sections on biochar amendments and the terms in the related equations in chapter 2 referring to biochar amendments to mineral soils.	Saint Lucia	Accepted with Modification	data density mentioned, including the study by Fang et al. (2014) which the cited Fuss et al (2018) article bases its Chapters 5 and 6 of Volume 4 include updates to the stock change factors for mineral soils. The refinement was asked to address mineral soil stock change factors. Addition of Biochar C to mineral soil is anthropogenic activity that impacts soil C stocks, and as such the stock change factors needed to be updated to address this impact. The development of these factors required a new calculation to address the influence of biochar on the C stocks of mineral soils given its very different nature and stability against mineralisation in soil. To make it more clear that the inclusion of biochar was to allow a more accurate assessment of C stock changes in mineral soils, biochar has been removed from the general soil equation (Equation 2.24) and the biochar term and its derivation have been added to Equation 2.25 which is specific to mineral soils. Action: Moved the ΔBCmineral equations from Equation 2.24 to Equation 2.25 and moved all explanitory text pertaining to biochar C to the text following this equation.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
1669	4	2			The biochar term is added to the calculation of C stocks in mineral soils without appropriate justification and without taking into account the large amount of literature questioning the positive and long-term sequestration effects of biochar addition. The section lacks a balanced scientific discussion of knowledge gaps and different scientific views related to the effects of long-term biochar application. Recent review e.g. summarized "Some fundamental mechanisms and the utilization of biochar in agroecosystems are poorly understood. These knowledge gaps mainly include the following aspects: it is significant to understand the interactions between biochar and soil microbial communities which may critically affect the release of CH4 and N2O. The exact service life of biochar is still rarely understood and (3) the maximum adsorption and desorption capacity of biochar are needed to be determined in further research." From this perspective it may be useful to add as a separate term in tier 3 approaches, but it is highly questionable whether it is good practice to add biochar amendments as a separate term as a tier 1 method given the existing knowledge gaps, lack of long-term measurements and uncertainties. We propose to delete at least the tier 1 approach for biochar addition. The method should request considerably more justification through long-term field measurements when biochar is included in GHG inventories in form of a separate biochar term.	,	Accepted with Modification	Chapters 5 and 6 of Volume 4 include updates to the stock change factors for mineral soils. The refinement was asked to address mineral soil stock change factors. Addition of Biochar C to mineral soil is anthropogenic activity that impacts soil C stocks, and as such the stock change factors needed to be updated to address this impact. The development of these factors required a new calculation to address the influence of biochar on the C stocks of mineral soils given its very different nature and stability against mineralisation in soil. To make it more clear that the inclusion of biochar was to allow a more accurate assessment of C stock changes in mineral soils, biochar has been removed from the general soil equation (Equation 2.24) and the biochar term and its derivation have been added to Equation 2.25 which is specific to mineral soils. The available literature was carefully reviewed and all studies that provided quantitiative experimental data pertaining to the retention of biochar C in soil were included in the analyses completed. Qualitative studies or opinions were not included Only experimental data that met the stringent quality criteria presented in Appendix 2A.2 were included. The references provided by the reviewer relate to the impact of biochar on soil fertility or crop yield. Recommendations about the agronomic impact of different biochars in different situations is outside the scope of the refinement. The refinement does not endorse biochar amendment as a best management practice.
					Table 2.3B gives for low and undefined temperature biochars an Fperm value of 0.13. A symmetric confidence interval of 0.04 - 0.23 is given. However, the Fperm value is a fraction and confidence intervals of fractions are generally not symmetric. It seems very likely that proper statistical analysis would indicate this value not to be significant, which would support exclusion of low and undefined temperature biochars. Inclusion of low and undefined temperature biochars should require material- and process-specific Tier 2 values for Fperm.		Accepted with Modification	The values were revised to asymmetric intervals, calculated as 95% bootstrap confidence intervals on the mean. This did not change the conclusions, and even the bootstrap estimates were close to symmetric. Action: No direct action was taken with respect to this comment. However, rather than using the regression line to predict Fpermp, all values within the temperature ranges (e.g. 350-450, 450-600 and >600 °C) were pooled to produce a revised set of Fperm values that have been entered into Table 2.3B. The uncertainties in these estimates were calcualted as 95% bootstrap confidence intervals and were close to symemetric. Thus the approach of expressing uncertainty in terms of ± a percentage deviation from the mean was retained.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
1685	4	2	2481	2483	The text extends the definition of natural disturbances from forests to other land uses such as woody grassland, undrained wetlands or undrained peatland without providing any justification or explanation what type of natural disturbances may occur on these land areas that are non-human induced and which cause non-anthropogenic emissions being beyond the control of and not materially influenced by a country. Please provide at least detailed examples and discuss what kind of justification is necessary to demonstrate that the impacts are non-human induced, non-anthropogenic, non materially influences and beyond human control for all the other land uses introduced in the method.	Germany	Rejected	This chapter specifically refers to General Methodology applicable to Multiple Land Categories. Disturbances listed in the ND definition are not land category-specific, they may occur in any of the land categories listed and they can contribute to IAV that is not due to anthropogenic actions. And the text already requires that countries that chose to disagregate the MLP E/R document their methods and assumtions as requested by the reviewer.
1687	4	2	2550	2555	There should be a clear definition of natural disturbances in the 2019 methodological supplement and element 2 of the generic methodological approach contradicts such clarity by allowing any country-specific definition of natural disturbances. Due to these shortcomings, we cannot accept an approach with a country-specific definition of natural disturbances. Certain parameters in the application of the natural disturbances definition may be determined by countries. But this is not the same as using a country-specific definition. Please clarify the relationship between the generic definition and any potential country-specific elements of such definition but delete the general reference related to a country-specific definition. Please also include the good practice requirements that have been used in previous IPCC guidelines related to the definition of natural disturbances, e.g. it is good practice that a Party demonstrates occurrences being beyond the control of, and not materially influenced by the Party by demonstrating practicable efforts to prevent, manage or control the occurrences which led to the application of the provisions.	Germany	Accepted with Modification	Text has been revised by stating that definitions of ND need to be "Consistent with the generic definition". This removes flexibility and by making it good practice to document the assumptions, it also increase transparency.
1689	4	2	2556	2592	The description of the generic methodological approach lacks precision, detail and the definition of good practice. In each step it should be inserted what good practice is related to the steps provided. The text should refer to "estimating the area affected by the disturbance" instead of "identification of lands" which is not precise language appropriate for IPCC Guidance. Inventory compilers should assess for each disturbance type that either the proportion of affected area is assessed accurately, if a approach is used at landscape level, or that each affected area is identified as being disturbed with georeferenced location, year and types of disturbances, when individual disturbed areas are assessed. Please also add that Parties should demonstrate that methods and algorithms used for detecting disturbances and disturbance type are suitable for the identification of areas affected by disturbances in a manner consistent with the Party's definition of forests and with the method how respective area or areas of land be identified in subsequent years.	Germany	Accepted with Modification	Most of the information provided in this section describes steps required to arrive at estimates of E/R which are explained in more detail, including the good practice requirements, in later chapters of the volume. Many of the requirements requested by the reviewer are provided in the more detailed chapters (e.g. how to estimate emissions from ND). The text states already that the land areas are to be identified (which clearly implies that an area estimate can be derived and this is required to estimate emissions, as described in later chapters). Nevertheless, text has been revised to include a footnote to indicate that "Methodological guidance on quantification of associated emissions and removals are given in the chapters with general guidance (chapter 2 and 3) as well in the category-specific chapters (chapter 4 and 6)".

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
1737	4	2	656	660	We would like to suggest adding "ALOS-2" as an example of satellite which can provide "fine resolution data with a pixel size smaller than 10 m". ALOS-2 was launched in 2014 and L-band Synthetic Aperture Radar (PALSAR-2) is onboard. The PALSAR-2 is capable of observing day and night, and in all weather conditions with 3m resolution. Please note that as the Global PALSAR-2 dataset is also listed in the Chapter3 Annex 3A.1 "Examples of International land cover datasets", the addition would likely enhance consistency between chapters. Regarding the values of 0.0110 (for CH4) and 0.000022 (for N2O) in Equation 2.26A, it might be worth to indicating in footnote how these factors are derived from the respective default CH4 and N2O emission factors presented in Table 4.3.2 for charcoal production (Volume 2, Chapter 4).	Japan	Accepted with Modification Accepted	We added references to ALOS and Sentinel 1 and also to upcoming space missions to be more specific here and also added a reference to reflect that. It has now been decided that emissions of non-CO2 GHGs (e.g. CH4 and N2O) during the heating process used to produce biochar will be recorded in the Energy sector of national inventories (see Volume 2, Chapter 4, Table 4.3.2.1 for values associated with charcoal production).
1739	4	2	1219	1219	To make it more comprehensive, other GHGs, such as CO, NOx should be added in Equation 2.26A. If they are not available, some explanations on why they are not on should be provided in foot note.	Japan	Accepted with Modification	It has now been decided that emissions of non-CO2 GHGs (e.g. CH4 and N2O) during the heating process used to produce biochar will be recorded in the Energy sector of national inventories (see Volume 2, Chapter 4, Table 4.3.2.1 for values associated with charcoal production).

					General comment: In spite of comments made on the SOD the guidance			
					on models and modelling in Volume 4 continues to be inconsistent with			
					the discussions of models and modelling in Volume 1. The most important			
					issues are related to the question of how to validate models, and the use			
			General		and need for validation against independent datasets. New comments			
2649	4	2	comment		have been made on this subject.	Canada	Noted	Please refer to specific comments responses

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
2651	4	2	General comment		General comment: the whole chapter 2 is difficult to read and, hence, to apply. It also confuses guidance with examples of what some countries have done, which is NOT guidance. Re-write by clearly separating concrete and practical guidance on quantifying emissions and removals, from examples and information boxes. Examples - which again should not be confused with guidance - should be provided together in an Annex.	Canada	Accepted with Modification	The word guidance was removed from the boxes examples; however the boxes are maintained within the main text to facilitate reading
2653	4	2	46	46	Section 2.6 on Inter-annual variability is part of the "additional guidance for Tier 3 methods" (following from the "Additional generic guidance for Tier 3 methods in Section 2.5), so would suggest for clarity that the Section title for 2.6 be revised as "Additional Guidance for Tier 3 Methods: Inter-annual variability". This would help to avoid any confusion as to whether this guidance applies to non-Tier 3 approaches.	Canada	Rejected	The guidance proposed is not limited to Tier 3 approaches.
2655	4	2	773		Reference is only made to drained organic soils. Organic soils may also be excavated, impacted through compaction, changes in vegetation cover resulting from various different land use changes. Since this is general guidance, the guidelines should clarify whether or not the generic guidance is applicable to these situations related to organic soil impacts that are not "drainage" per se.	Canada	Noted	There is guidance on these issues in the 2013 IPCC Wetlands Supplement, and it was beyond scope in the TOR to provide further guidance on organic soils in this refinement.
2657	4	2			This long list impacts readability and is not comprehensive in any case, please simplify and revise. Appears to be somewhat repetitive from Chapter 3, Volume 1, please assure that there is no repetition.	Canada	Accepted with Modification Noted	The list is not intended to include all factors, but to show the complexity of the factors influencing decomposition processes. Text was added to clarify this aspect. This box provides examples of the approaches taken by different countries to apply a Tier 3 approach to quantifying soil carbon stock change so the context is not the same as Chapter 3 in Volume, and so this box provides additional details about the methods that were not discussed in the uncertainty chapter.
2659	4	2		1698	Revised as: "In all cases models used in Tier 3 methods ensure higher accuracy only when they have been effectively validated against an independent data set, are correctly applied and capable of representing the population of interest." As is, the statement confuses precision of output with accuracy. Models can provide very detailed and precise output that is completely inaccurate.	Canada	Accepted with	We can agree (with the reviewer) and as per the initial text that higher accuracy of Tier 3 methods requires that " correctly applied and capable of representing the population of interest."However, that is the only requirement for higher accuracy. Validating against another data set does not influence the accuracy, but validation is of course useful as part of the process to develop a method that is more accurate. The act of validation itself has nothing to do with the accuracy of the method. The steps for correct implementation of models are outlined in the text following. Validation is included as a step. the text has been slightly modified to highlight that correct implementation is required and to achieve this the steps following should be worked through.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
2662			7000		Higher accuracy can only be assured when models are "validated" Modify sentence: only when they are correctly applied and validated, and are	Canada	Accepted with	We can agree (with the reviewer) and as per the initial text that higher accuracy of Tier 3 methods requires that " correctly applied and capable of representing the population of interest."However, that is the only requirement for higher accuracy. 2665	4	2	2087		It is not clear how "provide estimates of uncertainty for the estimated stock changes" could be considered a criteria of selection for a model. Remove and begin with: "uncertainty is reduced relative to	Canada	Accepted with Modification	restated that the model needs to be capable of quantifying uncertainty
2667	4	2	2109	2109	Data that is independent from what? When talking about validation (or evaluation data sets according to the authors wording) it is clear that the data has to be independent from the data that is used in calibration. But what should the calibration data set be independent of? Please clarify.	Canada	Accepted with Modification	There is bracketed text at the end of the sentence that clarifies what the calibration data should be independent of. Additionally the <i>good practice</i> text has been modified as a result of this and other comments to say "Calibration data should represent the population. In practice, this does not mean that all environmental conditions are covered, but that the original calibration data includes a range of the conditions existing the country that is representative of national circumstances."
2669	4	2	2126	2126	Please revise to say simply "countries should document calibration results".	Canada	Accepted with Modification	Text have been edited to simply and concisly say; In all cases it is good practice to document the calibration procedure and results.
2671	4	2	2160	2164	This paragraph is more about interpretation of research results than guidance, please revise or remove	Canada	Accepted	Text removed

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
		- Chapter			Community	Country ,	nespenses	/ Manioro Hotes
					The guidance in the introductory paras of Section 2.6 notes that "some" of			
					the E/Rs from managed land are characterized by high IAV (line 2388),			
					and as a result, this can make it "difficult to gain a quantitative			
					understanding of the role of human activities compared to the impacts of			
					natural effects" (Line 2398-2399). In response, the IPCC guidance			
					presented in this section is aimed at reducing "high" IAV. However, evidence clearly shows that natural disturbances - whether these result in			
					high IAV of emissions and removals or not - still affects the reported			
					estimates. See for example Kurz et al, 2018 - Quantifying the impacts of			
					, , , , , , , , , , , , , , , , , , , ,			
					human activities on reported GHG emissions and removals in Canada's			
					managed forest. As currently written, however, the IPCC guidance does not address circumstances where natural disturbances occur and are non-			
					anthropogenic in nature, but which are not characterized by high IAV of			
					emissions and removals. For example, when aggregating the impacts of			
					various types of natural disturbances at the national level for reporting in			
					GHG inventories, the process of aggregation may mask high IAV occuring			
					at the regional level. Therefore, any IPCC guidance aimed at clarifying the			
					impact of human actions on the reporteed estimates needs to not only			
					address high IAV related to natural disturbances, but all IAV related to			
					natural disturbances, provided that countries can show how human			
					impacts are distinguished from natural impacts. Specific text			
					modifications have therefore been included below for lines 2388, 2398,			
					2413, 2455, 2464, and 2480 to clarify that there is evidence that IAV (i.e.			
					not "large IAV") results in distortions in the reported estimates and that			
					this can be effectively addressed by separating anthro from non-anthro			According to the proposed guidance it is up to countries to

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
					To avoid using language associated with accounting-related decisions from the Kyoto Protocol, which is inappropriate to reflect directly in IPCC guidance, the language in this para should be modified to draw on the important concepts and definitions established through the KP, but in a more general way. Line 2469 should state that "natural disturbances are non-anthropogenic events or non-anthropogenic circumstances." A second sentence could then recall important concepts, e.g. that natural disturbances result in emissions and removals that are beyond the control of and not materially influenced by Parties. Consistent with proposed changes to lines 2388, 2398, 2413, 2455, 2464, 2480 about the need to address all IAV associated with natural disturbances, and not only "high IAV", suggest removing the reference to "significant" emissions from line 2470.			
2691	4	2	2469	2472	Footnote 15 should be also revised as follows: "Further information on natural disturbance definitions and approaches can be found in IPCC (2014)," Moreover, unlike the KP definition which was designed as accounting guidance for forest-related natural disturbances, the IPCC guidance should not restrict application to only forest lands, as evidence supports the application of this approach to non-forest lands as well. Removal of "defined" and keeping the reference to "in the context of AFOLU" in line 2469 help to clarify this.	Canada	Accepted with	Text has been revised to "avoid language" that could be perceived as "associated with accounting-related decisions form the Kyoto Protocol"; including the revision to the footnote as additional information rather than the place from which the definition was derived (as it is slightly different). About significant, since the method is about disaggregating GHG emissions/removals with high certainty, such clause to be significant is needed since insignificant fluxes cannot be identified/quantified with high certainty.
2693	4	2			This section does not provide any guidance for addressing the balance of emissions and subsequent removals in the instance where sequential natural disturbances occur on the same lands over time.	Canada	Accepted	Added "In the case of repeated disturbances on the same land, the time to reach balance is expected to increase." Note also that Kurz et al. 2018 does provide further information on the approach.
2695	4	2	2509	2509	Not clear how the 3 methods (annual to periodic, averaged or disaggregated by drivers) relate to following paragraphs	Canada	Accepted	The following paragraphs and table seek to document how methodological choices affect the IAV in estimates of E/R. Text was revised to improve clarity.
2697	4	2	2573	2583	By using actual fractions (one third) the concept could be easily confused. When suggesting mathematical constructs, authors should use mathematical equations. In general, however, this section seems overly prescriptive and it would be preferable if the authors were capable of developing some rules of thumb, as opposed to mathematical constructs.	Canada	Rejected	The text clearly states that the allocation of removals to the anthropogenic and natural components is in proportion to the allocation of emissions to these two components. This is the guidance. What follows is merely an example.

CommentID	D Volume Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
				The "carbon balance" rule introduces a methodological bias and is not			
				practical. 1. The approach is not quantitatively sound: assume 2 stands			
				with the same biomass, one in the anthropogenic component, the other			
				still in the disturbed component (because it has not reached its pre-			
				disturbed biomass yet). Harvesting those two stands in exactly the same			
				way will be reflected differently in the inventory, because the loss of the			
				growing sink will be reflected in the first instance but not in the second			
				one. In addition, the significance of this discrepancy will vary depending			
				on stands' pre-disturbed biomass, which is arbitrary. This will not occur If			
				stands are considered as "anthropogenic" as soon as they are eligible for harvest. 2. The approach is not practical: Foresters know when a tree is			
				ready to go to the mill, they do not know when carbon equivalency occurs			
				(i.e. decades after a disturbance). Let's try to keep the guidelines practical			As stated in rows 2564-2566 any C stock loss associated with a
				and applicable. Line 2494: Modify the sentence to: A fundamental			activity that occur after the disturbance is anthropogenic; so

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
								Text in Chapter 1 has been revised to further clarify the
								purpose of Chapter 2.6 is not to provide "guidance on
								accounting".
								Nevertheless, the authors disagree with the assessments made
								by the reviewer; in particular because the estimation of
								emissions from natural disturbances is covered in earlier
					Natural disturbances - there should be more focus on IAV here and less on			sections of the guidelines, and no changes are suggested in this
					other timescales and accounting. Estimation of emssions from natural			section to the basic methods for estimating emissions.
					disturbances is also not clear. Perhaps it's worth to wait until the science			Estimation of uncertainties in E/R is also covered elsewhere in
					develops here and clearer guidance could be given. Uncertainties related			the guidenace and not altered here. This section does not
					to changes due to natural disturbances should be clearly highlighted here			address the distinction between managed and unmanaged
					and elsewhere. Also, ways of distinguishing between managed and		Accepted with	lands (see Ogle et al. 2018) for a recent publication on this
2901	4	2	2420	2832	unmanaged land seems to be rather not straightforward.	Estonia	Modification	issue.
					Box 2.0D appears to focus on satellite-mounted LIDAR and SAR, but not			
					airborne (i.e. plane-mounted) applications. Suggest either adding airborne			
2544			650	670	applications to the box, or making the box's focus on satellite applications			We added text to say that it can be both airborne and
3541	4	2	653	6/2	clear.	America	Accepted	spaceborne instruments
					factoring out the inter-annual variability of emissions/removals resulting			
					from natural disturbances on managed land. It may be that the intent of			
					the new guidance is only to assist countries in disaggregating			
					emissions/removals associated with natural disturbances on managed			
					land so that they can better understand the impacts of their management			
					activity. This seems fine and could be a useful exercise for some countries. However, some parts of the chapter appear to suggest that the			
					comprehensive emissions/removals from managed lands associated with			
					natural disturbances need not be reported as part of inventory totals (e.g.,			
					lines 2490-2492, 2594-2599, 2782-2783, 2801-2802, and others), thus			
					leading to underreporting. This is not acceptable and the authors should			
					carefully review the entire section to ensure use of this guidance will not			
					be construed in this manner. Factoring out the emissions/removals is an			
					accounting approach and is not consistent with inventory reporting in			
					which the managed land proxy is used as the basis to separate natural and			
					anthropogenic emissions/removals. Additionally, the new guidance does			
					not make it sufficiently clear that addressing/factoring out emissions and			Authors agree with the Reviewer's interpretation of the intent
					removals from natural disturbances through accounting in the UNFCCC is			of the disagregation methods.
					already a well-accepted approach. While IPCC should not provide			
					guidance on accounting, the omission of this information makes it appear			Text of section 2.6.4 (and Box 2.2L) has been revised to make
					as if the only way to address natural disturbances is through the GHG			clear that is good practice to report both the total MLP E/R and
					inventory. In our view it is inappropriate to include guidance on			the disagregated components.
					separating emissions/removals from natural disturbances from			
					anthropogenic emissions/removals. This is an accounting practice, and not			However, the authors do not agree that it is appropriate to
					something that should be included in the IPCC inventory guidelines.			move the guidance to an annex.

								represent areas of land-use according to IPCC categories; and
								Tier 2 and 3 refer to the level of methodological complexity
								used to estimate emissions and/or revmovals; therefore there
								are not "interchageable".
								Nevertheless, authors have agree to introduce the following
								definitions in the glossary:
								Approach 1
								Represents land-use area totals within a defined spatial unit,
								which is often defined by political boundaries, such as a country, province or municipality.
								Approach 2
								The essential feature of Approach 2 is that it provides an
								assessment of both the net losses or gains in the area of
								specific land-use categories and what these conversions
								represent (i.e., changes both from and to a category). Thus,
								Approach 2 differs from Approach 1 in that it includes information on conversions between categories, but is still only
								tracking those changes without spatially-explicit location data,
								often based on political boundaries (i.e., locations of specific
								land-use and land-use conversions are not known).
								Approach 3
					In the report, the terms "Tier 1, 2 and 3" and "Approach 1, 2 and 3" seem			The key defining characteristic of Approach 3 is that it is both
					interchangeable. The first term is clearly defined in the glossary (Glossary			spatially and temporally consistent and explicit. Sample-based,

CommentID	Volume	Chanter	Fromline	Toline	Comments	Country	Responses	Authors' notes
CommentID	Volume	Chapter	Fromline	Toline	The temperature thresholds allocating 1.5 times more stability to biochars produced at above 600 °C are inappropriate. Please consider adjustments to the text. Some studies show that a temperature threshold of 370 °C is sufficient for producing stable biochar (Budai et al., 2016), and several studies show an increase in biochar stability with pyrolysis temperature (comparing pyrolysis temperatures of 450 and 550 °C for example) (Fang et al., 2014). However, greater stability of biochars produced above 600 °C compared to biochars produced in the range of 450 to 600 °C has not been documented and the source of data used here (Figure 2A.2-1) is not convincing of this trend either. There should not be a large increase in the FPERMp factors for biochars that have undergone more intensive carbonization. The categories (currently based on temperature ranges of 450 – 600 °C and >600 °C) should be eliminated or reduced: the FPERMp factors for all biochars meeting a minimum threshold (O/Corg < 0.25 and/or H/Corg < 0.7) should be a single value (0.43). Most change in biochar stability and reduction in biochar yield during production occurs at low temperature gradients, not in the range of 600 °C. Results from laboratory studies on biochars produced under highly controlled conditions indicate that an increase in persistence above a fairly low temperature threshold (450 °C) is not very strong with individual studies showing no difference (see Budai et al. 2016) or small differences in the range of 20%. The consequence of the current large difference is that producers will favor higher pyrolysis conditions, while at this time the environmental benefits of high- and low-temperature biochars is still	Country	Responses Accepted with Modification	Authors' notes The calculation of Fperm has been changed from a linear regression to heating temperature categories to account for the known non-linearity between pyrolysis temperature and biochar C persistence. Justification for this change has been added to Annex 2A.2. The Tier 1 methodology was based in temperature rather than biochar properties (such as the mentioned H/Corg or O/C ratios) to facilite accounting in the framework of a Tier 1 method. H, O, and C analyses using Dumas combustion requires specialized equipment that is not available in many countries. In addition, costs for analyses will also constrain the applicability of the method. Mandating the use of elemental ratios will reduce the ability to account for biochar additon to mineral soils. Countries with the ability to measure biochar properties are encouraged to use the recommended Tier 2 and 3 methods; appropriate reference was added to the method and appendix. The text in Annex 2A.2 defining how Fperm was calculated was revised. The revised values of Fperm have been added to Table 2.3B. Text has also been added to Annex 2A.2 defining the potential use of O/C and H/C ratios in higher Tier methods.
3787	4	2	1214	1215	In equation 2.26A the term accounting for methane and nitrous oxide emissions (BCTOTp·GWP-CH4·0.011)+ (BCTOTp·GWP-N2O·0.011) during pyrolysis should be omitted. Reasoning: 1. In industrial pyrolysis plants syn gas (pyrolysis gas) is flared or used for energy/fuel production. Emissions of methane and nitrous oxide of these plants are neglectable. Values of 0.011 and 0.000022 in the equation are based on small, low technological kilns studied by Cornelissen et al. (2016) where syn gass is emitted without any treatment. 2. Emissions from pyrolysis plants should be taken into account in inventories for industry. Biochar, biooil and syn gass are the main products from pyrolysis. Pyrolysis is an industrial process for energy and fuel production equal to waste incineration, and emissions should be assigned to the industrial sector and not accounted for when biochar is used for carbon sequestration in soils.	<u>Norway</u>	Accepted	It has now been decided that emissions of non-CO2 GHGs (e.g. CH4 and N2O) during the heating process used to produce biochar will be recorded in the Energy sector of national inventories (see Volume 2, Chapter 4, Table 4.3.2.1 for values associated with charcoal production).

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
					Footnote 8: Please add that the Table 4.3.2 is in Volume 2, Energy, chapter 4.3.2.1 SOLID TO SOLID TRANSFORMATION PROCESSES		Accepted	It has now been decided that emissions of non-CO2 GHGs (e.g. CH4 and N2O) during the heating process used to produce biochar will be recorded in the Energy sector of national inventories (see Volume 2, Chapter 4, Table 4.3.2.1 for values associated with charcoal production).
3791	4	2	1218	1218	Please add "Corrections for GWP of CH4 and N2O do not apply if syngas is used for bioenergy purposes".	Norway	Accepted	It has now been decided that emissions of non-CO2 GHGs (e.g. CH4 and N2O) during the heating process used to produce biochar will be recorded in the Energy sector of national inventories (see Volume 2, Chapter 4, Table 4.3.2.1 for values associated with charcoal production).
3795	4	2	1227	1220	To be consistent with previous definition of permanent storage, why not take 100 years for permanent storage (instead of 1000). Alternatively please explain the choice of time horizon.	Norway	Accepted	The permanence period has been changed to 100 years to be consistent with the permanence requirements for other sequestration measures. All permanence values were recalculated to 100 years and used to replace values previously entered for a permanence period of 1000 years. All references to 1000 years in the text have been changed to 100 years.
3797	4	2	1230	1230	The word "produced" needs to be changed to "released to the atmosphere": The release of CH4 TO THE ATMOSPHERE during pyrolysis is a problem, but not its capture and use as bionergy (there it is beneficial and only concerns the energy sector). With well engineered biocharpyrolysis systems, no CH4 is released to the atmosphere, but CH4 is produced by the process, use in the bioenergy sector (where it is relased to teh atm as CO2). This is why it is crucial to replace "produced" by "released to the atmosphere.	Norway	Accepted	It has now been decided that emissions of non-CO2 GHGs (e.g. CH4 and N2O) during the heating process used to produce biochar will be recorded in the Energy sector of national inventories (see Volume 2, Chapter 4, Table 4.3.2.1 for values associated with charcoal production).
3799	4	2	1232	1232	Need to add to explanation to N2O discounting: "if not used in a bioenergy context": If pyrolysis is effciently used (as it should) for both biochar and bioenergy/syngas production, the emisison associated with the bioenergy production need to be accounted in the energy sector, and not in the Land / C sequestration.	Norway	Accepted	It has now been decided that emissions of non-CO2 GHGs (e.g. CH4 and N2O) during the heating process used to produce biochar will be recorded in the Energy sector of national inventories (see Volume 2, Chapter 4, Table 4.3.2.1 for values associated with charcoal production).

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
					It should be highlighted that C content factor for the different feedstocks varies with pyrolysis temperature. Biochar produced at higher temperatures contains higher C levels.	,	Rejected	No temperature response is included in Table 2.3A (FCp). The reason temperature was not included is as follows: Although there is a modest increase with temperature in the carbon content of biochar on an ash-free basis, this is mediated by the fact that ash content of biochar (as a fraction of total weight) also increases with temperature. These two effects approximately cancel out, leading to only a negligible (much smaller than the uncertainty and not significant) change in carbon content as a fraction of total weight. Accordingly, no temperature response of FCp was used, because FCp is expressed per unit total weight of biochar (including ash).
3801	4	2	1261	1262		Norway		
					Elemental ratios should be the default measure of biochar quality, not pyrolysis temperature: Pyrolysis temperature is the most important determinant of biomass conversion, but it is unreliable as a quality index due to the difficulty of controlling and measuring it. This is especially true at lower pyrolysis temperatures of 400 °C and below where exothermic reactions are predominant (Budai et al., 2014). Heat transfer limitations often result in uneven pyrolysis of the biomass, with exothermic reactions remaining localized and measurements of the reactor temperature not necessarily representing the actual temperature experienced by the material. Therefore, elemental ratios of H/C reflect much better than temperature, the degree of carbonization (degree of biomass conversion) of the biochar and hence its quality. The suggestion is that measured biochar properties (atomic ratios of O/Corg and/or H/Corg) be used to define the FPERMp factors in Tier 1, not production temperature, as production temperature is difficult to monitor. Temperature measurements taken often do not reflect the actual temperature experienced by biomass in a reactor. Elemental analysis is a standard measurement that can easily be included in biochar quality assessment that would need to be performed anyway to ensure product quality (heavy metal content for example).		Noted	The calculation of Fperm has been changed from a linear regression to temperature categories to account for the known non-linearity between pyrolysis temperature and biochar C persistence. Justification for this change has been added to Annex 2A.2. The tier one methodology was based on heating temperature rather than biochar properties (such as the mentioned H/Corg or O/C ratios) to facilite accounting in the framework of a Tier 1 method. H, O, and C analyses using Dumas combustion requires specialized equipment that is not available in many countries. In addition, costs for analyses will also constrain the applicability of the method. Mandating the use of elemental ratios will reduce the ability to account for biochar use. Countries with the ability to measure biochar properties are encouraged to use the recommended Tier 2 and 3 methods; appropriate reference was added to the method and appendix.
3803	4	2	1268	1269	If the term in equation 2.26A accounting for methane and nitrous oxide emissions is not omitted (as suggested for Eq. 2.26A), it should at least be emphasized in tier 2 and 3 that methane and nitrous emissions can be estimated based on measurements.	Norway	Accepted with Modification	It has now been decided that emissions of non-CO2 GHGs (e.g. CH4 and N2O) during the heating process used to produce biochar will be recorded in the Energy sector of national inventories (see Volume 2, Chapter 4, Table 4.3.2.1 for values associated with charcoal production).

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
CommentID	Volume	Chapter	Fromline 362		Without any manipulation, we carried out a short, limited test of the steady-state model with data from two sites of the German Permanent Soil Observation program. The results showed both locations in equilibrium, i.e. no changes with respect to the temporal trend and carbon stocks calculated by the model deviated significantly from the level measured at the stations (ca. + 40%, respectively ca 70%). Only by intensively manipulating the input data of the model (C-Input) to reach the actual initial C-stock of the soil, we received results which correspond in trend and height approximately to the values of the measured values. A small, additional test showed that also the temperature sensitivity of the model does not seem very pronounced. Admittedly, this was only a superficial and not at all comprehensive check of the model. A comprehensive test would require to check significantly more locations and to evaluate the uncertainties of the model. Such additional validation should be conducted before this model is included in the guidelines. We also seek guidance, why specifically this model should be endorsed by the guidelines as other models are also available. We understand that the possibility of using an asymmetric system with regard to the transitional period is introduced in order to avoid over- or underestimation of land-use change emissions from/ to cropland. This is commendable but currently under the existing rules not applicable. Most of the relevant literature refers to the "fast out-slow in" - principle (e.g. Poeplau et al. 2011), mostly based on paired site studies. However, other studies do not show this asymmetry in carbon stock changes. Apart from the fact that we ultimately do not know what is the truth, against the background of other basic rules of the guidelines, this method does not seem practicable. For example: According to Poeplau et al. 2011, in the case of land use change from, e.g., grassland to cropland, the carbon losses occur within 18 years, whereas in the opposite direction the	Germany	Responses	Authors' notes We appreciate the evaluation by the reviewers. As a nonobligatory Tier 2 method, it will be up to each country to determine if they want to adopt the method based on such country-specific assessments. The Tier 2 method provides general estimates of C stocks given more country specific data on C inputs, tillage, soil texture, and weather but does not include country-specific data on initial soil C stocks. Therefore, these C stock estimates are not expected to necessarily provide an accurate estimate of soil C stocks of particular location. If a country wishes to include the effect of measured initial soil C stocks on estimates of C stock changes, then it would be best to use a Tier 3 methodology. ANNEX 5A.3 provides the wide range of location whose obsevation were used to fit the method parameter values. We cannot provide a general method uncertainty since that depends on the uncertainties of the country-specific inputs of texture, C input, and weather. The uncertainties of the parameters are provided in Table 5.5A and the compiler can use these with the those of country-specific inputs to estimate the uncertainty of method for their country. We added a sentence in 5.2.3.1 where the method is introduced (L365) that indicates the scope of use. It sufficiency for that scope is the rationale for the selection of the particular method. Also, the three pool steady state solution has been published in the literature. A country is not obligated to use it and can choose to base C stock change estimates on any veririfed model in a Tier 3 application. Good point. We have a added a sentence to point out this issue out to complilers.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
CommentiD	Volume	Chapter	Fromline	Toline	Table 6.2: "Moderate degraded grassland" categorie for FMG was in 2006 splits in 3 climate zones in the new guideline this category is replaced by "intensity grazing" (without climate division) and overall	Country	Kesponses	We added sentences to Annex 6A.1 that the categorization was revisited with the literature and concluded that the moderately degraded management factor had been determined from a non-rigorous and non-reproducible interpretation of scientific literature to categorize particular grazing regimes into "moderately degraded" and comparative "non-degraded" states. The original paper authors almost entirely did not refer to or define either the non-degraded or moderately degraded states, only the grazing intensity in terms of light, moderate, and heavy. This was different from the severely degraded state where there several papers that referred to severely degraded pasture and it was clear this referred to the state of both the vegetation and soil. In fact, outside of severely degraded, there was only few studies that reported a grassland vegetation state for each grazing regime to develop a relationship between grassland vegetation and soil C stocks. Therefore, we redid the analysis using the grazing intensities as defined by the original paper authors to derive a factor for high intensity grazing versus light to moderate grazing. The high grazing intensity factor is more scientifically defensible than the moderately degraded state factors in the 2006 GL. There was insufficient data to reliably derive the high -intensity grazing factor for different climates. Regarding activity data, for policy purposes, many countries collect data to know if they have too little or too much livestock for their grassland areas so may have
203	4	6	122	123	decreased from 0.96 to 0.90. This change is little justified with reference in the text: lack of analysis.	France	Accepted with Modification	activity data on grazing intensities relative desired grazing intensity and so can identity areas with high intensity grazing.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
					Comment: (not just specific to the referenced lines) It is going to be difficult to distinguish high intensity grazing from Improved-High input grazing. If graziers have undertaken multiple improvements - fertiliser, species improvement - then there is high stocking capacity, so will usually have high grazing intensity. ie would not be decribed as "nominally or moderately grazed" But if well-managed, will not show signs of "change in species composition" - so is it "High intensity grazing" or "Improved grassland"? It is likely that such a system will have same SOC as a lowerinput system (eg Young et al, 2016) ie will overestimate SOC if classed as Improved grassland but will underestimate if classed as High intensity grazing. There should be an additional class of "High intensity, not degraded", with a factor of 1.0. Otherwise, revise the description of high-intensity to remove all reference to degradation and change in species			We agree that the way the decison tree is presented the compiler could be confused about having to make a grazing intensity decision for high productivity improved grasslands. We addressed this by changing the order of the flowchart so that decision on high intensity grazing is made after the grassland productivity decision so that high intensity grazing decision is only required for unimproved grassland. We also improving the definition as: "High intensity grazing is defined as grazing that deteriorates the condition and/or long-term recovery capacity of the vegetation compared with the vegetation state under nominal to moderate grazing intensity. High intensity grazing does not refer to stocking rate and duration only, but to the stocking rate and duration in relation to grassland productivity and resilience. This may be called a moderately degraded condition but high intensity grazing does not lead to the severe degradation such as is caused by relentless overgrazing. High intensity grazing also includes land where vegetation is frequently cut and removed equivalent to high intensity grazing and without application of any animal manure."
					composition, to ensure that all high intensity grazing is allocated a factor of 0.9, to avoid overestimating SOC in improved pastures that are		Accepted with

								Good point. We have a added a sentence to point out this issue out to compilers.
					We understand that the possibility of using an asymmetric system with regard to the transitional period is introduced in order to avoid over- or			
					underestimation of land-use change emissions from/ to cropland. This is			
					commendable but currently under the existing rules not applicable. Most			
					of the relevant literature refers to the "fast out - slow in" - principle (e.g Poeplau et al. 2011), mostly based on paired site studies. However, other			
					studies do not show this asymmetry in carbon stock changes. Apart from			
					the fact that we ultimately do not know what is the truth, against the			
					background of other basic rules of the guidelines, this method does not seem practicable. For example: According to Poeplau et al. 2011, in the			
					case of land use change from, e.g., grassland to cropland, the carbon			
					losses occur within 18 years, whereas in the opposite direction the			
					transition period is in the range of 100-200 years. As land use is usually			
					hard to trace back for the 20 default years, it seems impossible for 100- 200 years. The compiler does not know, e.g., in the case of a LUC from			
					grassland to other land, whether the area is in steady state or at what

1103	4	/	222	225	wetlands category.	Finland	Noted	should still be addressed by the compiler.
					2019 Refinement introduces a new concept in the GHG inventory to factor out emissions (removals). It is not clear, if this method is intended to be optional or mandatory for a country which is going to included emissions from flooded land in its inventory (in lines 276-277: with practical consideration for application of the methods by compilers). If it is optional to factor out emissions that would otherwise occur from unmanaged land without conversion to managed flooded land, this guidance shall be preferably placed in appendix to this Chapter. Whether it is optional or not to apply this method, more justification for it is needed, because it is not in line with GHG inventory principle to report actual emissions/removals. Factoring out emissions/removals means that a methodology to estimate emissions/removals from unmanaged lands would have to be developed - thus the 2019 Refinement should provide the appropriate guidance at the same time with guidance on flooded land factoring out. Also, the method is not consistent with the managed land proxy. Factoring out is not used for other land use categories or			We agree that the general issue of emissions associated with conversion of unmanaged land to managed land is not unique to flooded lands. However, there was a mandate in the TOR to develop these methods, we have provided a clearer justification for this approach for flooded lands in the Introductory section. The following sentence has been added: "Inventory compilers may choose to report total emissions from Flooded Land, in accordance with the Managed Land Proxy, or to factor out emissions and removals associated with
1105	1	7	245	291	emissions/removals from other sources. Thus, the emissions from flooded lands would be counted differently even under wetlands category.	Finland	Accepted	Unmanaged Lands that occurred before conversion to Flooded Land. "
	-	,			It is mentioned that factoring out is not applied to flooded land which has been managed land before the conversion as they are included in the inventory from the baseline year. What does 'baseline' year mean? Base year? The base year can differ between countries, so how this should be taking into account? For many Annex I countries the base year is 1990. If a managed land is converted to flooded land e.g. in 2020, it is possible that			Text modified in line 295. No reference is now made to base

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
1113	4	7	768	770	It is left to inventory compiler to choose whether to report emissions from drainage ditches within flooded land (wetlands category), or under other managed land categories. If the ditches are an essential part of the land area, like it is in the case of drained forest land/cropland, the emissions from ditches should be reported in forest land/cropland category and not under wetlands. Please, reconsider the text.	Finland	Noted	This decision depends on national circumstances and therefore needs to be remain flexible.
1115	4	7	899	901	It is discussed about how to estimate the area of ditches in agricultural lands. Is it suggested to report the emissions from ditches in wetlands category? Some countries may have so wide ditches on croplands/grassland that it is practical to report separately the fields and the ditches. If this is the case, could it be clarified in the text. Normally the ditches are reported under cropland/grassland categories.	Finland	Accepted	The following text has been added: "For these areas, inventory compilers may choose to report these emissions within the appropriate land category, or separately in the Flooded Lands category."
1117	4	7	975	976	Biomass removed from an area before impoundment shall be reported according to the guidance given in Chapter 2 (e.g. 2.3.1.2 estimating change in carbon stock in biomass), not according to the guidance given for HWP. To avoid missunderstanding, it would be useful if in the text it were mentioned that these emissions from removed carbon stocks shall be reported under flooded land category. Thus, the emissions in the year of conversion can be different from the emissions in the subsequent years.	Finland	Accepted	Accepted, the reference was corrected; the methodology for CO2 emissions and removals with LUC is indeed described in Vol. 4 Chp.2. It is important that C transfer and emissions prior to flooding be reported and not double counted. Carbon losses due to disturbances or transfered to another pool (e.g. HWP) are tracked with methodologies describe in Vol. 4 Chp.2. We believe that it is more efficient to track theses changes in the land use prior to flooding and that emissions due to flooding start at flooding than to modify the accounting of flooded land to consider these pre-flooding changes.
1119	4	7			Default emission factors for CO2 emissions are given in Table 7.16. It is unclear what emissions these EFs covers. It would be useful for inventory compilers, if a more detailed description would be given in the text on what emissions are included in these EFs (biomass, DW, SOM?). Do data behind model (that has been used to derive EF's) include situations when woody biomass for instance has been removed before flooding and situations when woody biomass has been left as it is? Do data behind EF's make a distinction between different soils (mineral, peat) and ground vegetation covers? Please give guidance to inventory compilers in line with 'the EF's in Table 7.16 represent following cases: woody biomass left/removed, soil is mineral/peat, dead organic matter stock"	Finland	Rejected	The methodology and its rationale are explained in more detail the Annex. More specifically A7.1.2.2 (I.2085-2126). At tier 1 level, there is no distinction between soil types, however, climatic zones contraint somewhat the values. While different organic matter pool contribute to the surge of CO2 following flooding, their contribution is not individually modelled. the abudnant amount of reservoir emission measurements for reservoirs has made possible to develop estimates of net postflooding CO2-C emissions taht are scaled to yearly values. The anoxic conditions felow a few mm and the lack of knowledge on the degradation dynamics of individual OM pools in the reservoir have prevented the development of a more specific appraoch at Tier 1.
1119	4		10//	1080	Please revise "flooded <= 20 years prior to inventory" to "flooded <= 20	FIIIIdilu	nejected	appraocriat ner 1.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
1195	4	7	906	907	#2: Additionally, Tier 1 emission estimates for Other Flooded Land appear to be based on system capacity, that is the assumption that all structures under Other Flooded Land are filled to capacity throughout the year, and emission estimates are then based on that. This approach may result in an over-estimated methane emission value. Could additional guidance be provided on the application and range of values for a Tier 1 "correction factor" to account for system utilisation? System utilisation accomodates temporal changes in pond/ditch water level and area (and therefore methane emissions) associated with weather/climate variablity, usage and seepage losses.	Australia	Accepted	The following text has been added to the activity data section we have also added "If waterbodies vary substantially in their spatial extent through the year, the annual average (rather than annual maximum) inundated area will provide the most appropriate basis for flooded land area estimation"
1197	4	7	906	907	#3: could the references to Tier 2 and 3 models identify system utilisationas an important factor to account for temporal variability of emissions due to observed and/or modelled changes in pond level associated with weather/climate variability, usage and seepage losses.	Australia	Accepted	The following text has been added under Tier 2: "Additional management-related factors may be considered if these affect emissions, for example if waterbodies are subject to large seasonal or short-term changes in water level and area, this may produce different CH4 emissions that a waterbody with the same average surface area but more constant water levels."
1283	4	7	136	139	A clear definition of what a wetland is - needs to be provided. The current definition states land that is "Flooded Land is comprised ofland area flooded" But it is not clear for how much period if inundated, it can be considered as a wetland	India	Accepted	A more comprehensive definition of the types of Flooded Land considered in the chapter has been provided, with reference to the definition given in the 2006 Guidelines. We have clarified the distinction between flooded lands and other wetlands, and referred to the 2013 Wetland Supplement for guidance on the latter.
1511	4	7	135	1269	Guidance for estimating total flooded land emissions and removals should be consistent with the managed land proxy. Therefore, the total emissions reported should reflect the actual GHG fluxes that occur in lands classified as "managed". Additional methodologies for estimating emissions and removals that would occur if the flooded land remained unmanged ("factoring out") should be provided as an option that may be used by countries that choose to consistently and transparently report such counterfactual emissions and removals. Such methodologies should be provided for information only, and it should not add guidance, nor overrule guidance provided.	EU	Rejected	We have provided methods for estimating the total emissions from flooded lands that are consistent with the Managed Land Proxy. To increase transparency we have modified the text and reporting tables to include both total and net emissions.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
					The chapter describes a factoring out methodology. It mainly focuses on			
					including unmanaged land into the GHGI. Even though factoring out was			
					requested in the mandate for drafting this chapter it seems the wrong			
					guidance for reporting. If considered at all, it will be part of an accounting			
					guidance, but this is not within the scope of this Refinement.			
					The section seems to touch upon a general issue when unmanaged land			
					becomes managed land, but this is not specific for flooded land. The			
					justification for high carbon loss/gain is also not a specific criterion for			
					flooded land, only. What about previously unmanaged forest land			
					becoming included into managed land? GHG removals in unmanaged			We agree that the general issue of emissions associated with
					forests are enormous. Strict adherence to the Managed Land Proxy should be maintained for			conversion of unmanaged land to managed land is not unique to flooded lands. However, have provided a clearer justification
					estimating emissions and removals for the inventory for flooded land			for this approach for flooded lands in the Introductory section.
					reported in greenhouse gas inventories. Therefore, if the report retains			We disagree with the comment that we have not followed the

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
1533	4	7	245	281	This section on factoring out should clearly state that total emissions/removals from flooded lands based on the managed land proxy should be reported as part of national greenhouse gas inventories, regardless of whether Parties also choose to report emissions/removals that would occur if the flooded land remained unmanaged.	EU	Accepted	We have added text that addresses reporting of both Net and Total emissions as well as modifying the reporting tables. The following sentence has been added: "If a factoring out approach is applied, it is good practice to provide transparency by reporting both total and net emissions; otherwise the country should report the total emissions if net emissions are not estimated. Furthermore, if inventory compilers choose to factor out natural CH4 emissions from wetlands, it is also good practice to simultaneous factor out the loss of any natural CO2 sink in the that would otherwise have occurred if the land remained unmanaged"
1535	4	7	296	930	Factoring out of emissions that would otherwise have occurred had the flooded land remained unmanaged is not consistent with the principles of the managed land proxy. The guidance should not therefore promote the use of such factoring out as good practice for inventory reporting. These methodologies should only be retained in the report if it is clearly stated that it is there to provide information in case Parties wish to use it for purposes other than reporting of greenhouse gas inventories.	EU	Accepted	The following text has been added before Figure 7.2: "If a factoring out approach is applied, it is good practice to provide transparency by reporting both total and net emissions; otherwise the country should report the total emissions if net emissions are not estimated. Furthermore, if inventory compilers choose to factor out natural CH4 emissions from wetlands, it is also good practice to simultaneous factor out the loss of any natural CO2 sink in the that would otherwise have occurred if the land remained unmanaged"
1537	4	7	1840	1858	This box should be labelled as for information only. As described above, guidance for inventories should be based on the managed land proxy. The methodology described in this box could be used for other purposes such as accounting but reporting in greenhouse gas inventories should be based on strict adherence to the Managed Land Proxy.	EU	Rejected	We were mandated by the IPCC Panel to develop "consistent methodologies that take into account factoring out of emissions that would otherwise occur in the absence of the flooded area for estimating CO2 and CH4 emissions from flooded lands". We consider that the issues raised here are a matter for the IPCC plenary, and do not relate to the robustness of the science.
1571	4	7	245	281	We are concerned that the new guidance on how to factor out emissions (removals) that would otherwise occur from unmanaged land is not in keeping with the IPCC's guidelines for other sub-sectors, and is more relevant for accounting than for reporting. The IPCC should not be providing guidance on such accounting methods, and we are not convinced that the methods provided are sufficiently scientifically robust, especially given that the definition of managed land can be interpreted in different ways by different countries. If this guidance remains in the refinement we fear that the integrity of NGHGIs will be compromised.	Saint Lucia	Rejected	We were mandated by the IPCC Panel in the TOR to develop "consistent methodologies that take into account factoring out of emissions that would otherwise occur in the absence of the flooded area for estimating CO2 and CH4 emissions from flooded lands". We consideedr that the issues raised here are a matter for the IPCC plenary, and do not relate to the robustness of the science.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
					General comment: The wetland chapter introduces for the first time in the			
					LULUCF sector methods of factoring out emissions which would naturally			
					occur before an unmanaged land is converted to a managed wetland. It is			
					recommended to strictly stay within the managed land proxy in the way			
					that all emissions at managed lands are considered as human induced and			
					counted (no factoring out of natural emissions) in order not to represent a			
					precedent for other such cases. A decision of possible and principal			
					factoring out of previous natural emissions would require a thorough			
					analysis of the whole issue including unintended side-effects (also			
					concerning other subcategories and -sectors) and a related general			In principle, we agree that it would be useful to consider the
					decision and mandate. Since this does not exist, it is recommended to			implications for all land uses, but in practice, the TOR did not
					leave out any ways of factoring out emissions in the IPCC GL refinement. It			give the authors this broad scope, requesting a factoring out

2747	4	7	204	204	What's the difference between drainage channels and ditches?	Canada	Accepted	We have followed the Ramsar definition of linear human-made waterbodies here, which appears as either 'canals and drainage channels, ditches' or 'canals and drainage channels or ditches'. We consider the last two categories to be largely interchangeable and for simplicity have therefore (apart from referring to both categories in the definition) amended the guidance to refer to ditches only.
2749	4	7	906	907	General comment on chapter 7: The guidance in the Final Draft It is not consistent with the treatment of emissions and removals in the rest of the AFOLU guidance. The Factoring Out approach would lead to comparability issues if countries did implement it and as such can certainly not be provided as default methodology: see lines 2384-2385 of chapter 2, stating that " the Managed Land Proxy is the only universally applicable approach to estimating anthropogenic emissions and removals in the AFOLU sector". There are two options to maintain the integrity of the IPCC guidance in this 2019 MR, in spite of these inexplicable "Factoring Out" provisions. 1. Return to the approach used in the SOD and put the factoring out in a box as an example and not as guidance. 2. Group all factoring out in a new section "Basis for future methodological development" - allowing for such a time in the future when improved scientific understanding and quantification of "anthropogenic emissions and removals" will allow a scientifically credible implementation in inventories. As stated in chapters 1 and 2 of volume 4, the science currently does not support such "factoring out" approach as is proposed here.	Canada	Rejected	We agree that this method creates an inconsistency with other land uses, and also that there may be other relevant emissions that could be factored out with conversion to those categories. However, we were mandated by the IPCC Panel in the TOR to develop "consistent methodologies that take into account factoring out of emissions that would otherwise occur in the absence of the flooded area for estimating CO2 and CH4 emissions from flooded lands". We consider that the issues raised here are a matter for the IPCC plenary, and do not relate to the robustness of the science.
2751	4	7	0	0	General comment on chapter 7: if the goal is to better reflect the impact of activities on the atmospheric concentration of GHGs, then the "factoring out" of methane emissions from un-managed wetlands should be limited to one decade, that is the average time it takes for methane to oxidize in the atmosphere. Factoring out of methane emissions should certainly not be applied to "flooded land remaining flooded land". Re-phrase so it is consistent with chapter 1 and 2 of volume 4: "However, it is typical good practice for the greenhouse gas emissions in the AFOLU	Canada	Noted	While CH4 can oxidized in the atmosphere on the time scale of a decade, the emissions themselves can occur over a much longer period. The 20 year threshold is used for consistency and to reflect the different emission rates in these two time periods.
2753	4	7	256		sector"	Canada	Accepted	Inserted "good practice"
2755	4	7	258	260	Delete the two sentences starting with "Special considerations": 1st sentence: there is absolutely no scientific basis supporting a blanks statement on higher pre-flooding emissions specifically on un-managed land. 2n sentence: the point of the entire IPCC guidelines is to provide guidance on quantifying emissions, not make gross and unverifiable assumptions on when land-use change have a large or small impact on emissions.	Canada	Accepted	The sentences referred to have been removed, and the paragraph has been revised to make it clearer which preflooding emissions and removals are relevant to the 'factoring out' issue.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
					Box 7.1 does not provide sufficient guidance in to implement a methodology. Rather, provide a brief discussion of the challenges in quantifying the emissions and removals in sedimentation in the		Accepted with	The intention of box 7.1 is not to provide the methodology to estimate carbon burial. The box reports the challenges to estimate the portion of the carbon burial that can be attributed to the reservoir construction. The box has been improved. For higher Tiers the box brings some information for the compilers: "For the development of higher Tier methodologies for carbon accumulation in reservoirs, an important guiding principle is that only the portion of the carbon permanently buried in reservoir sediments that would not have been stored elsewhere in the hydrological network (including the coastal ocean) could potentially be considered as an offset to reservoir
2757	Δ	7	578	599	uncertainty section, not in the methodology portion.	Canada	Modification	greenhouse gas emissions."
	4	,			Assure that it is clear what equations or parameters apply to what "other constructed waterbodies" For example the title of Equation 7.19 is "annual emissions from other constructed waterbodies", but the parameter, "FCH40ther" is labelled as the total annual flux of methane			
2759	4	7	760	929	from ponds and channels.	Canada	Accepted	We have check and updated equations accordingly
2761	4	7	1040	1041	It's not clear how this is related to the presence of a river prior to inundation or if the reservoir is a small expansion of a natural lake.	Canada	Rejected	The comment indicates that the proportion of the area that is newly flooded can vary greatly among reservoirs. The EF is dependant on the soil C stock of the newly flooded land.
2825	4	7	136	296	Brazil is in favor of the version presented in the final draft. The proposed methodology fully meets the mandate set by the 44th plenary session of the IPCC in 2016, which prescribes that the refinement exercise should "update the CO2 emission factors for lands converted to wetlands and develop- based on a comprehensive review of the available literature and methodology- consistent methodologies that take into account the emission factor and removal that would occur in the absence of the flooded area to estimate CO2 and CH4 emissions from wetlands (both land converted to flooded land and flooded land remaining flooded). In order to reinforce this position, recent studies show that it would already be possible to discount the permanent burial of carbon in the sediment of the reservoirs using a lower Tier (2) than that proposed in this methodology.	Brazil	Noted	Box 7.1 has been improved. There was a problem when converting the Word (and
2903	4	7	282	าดา	Figure 7.2 - present a clear figure please.	Estonia	Accepted	illustrator embedded figure) into PDF format. We have corrected this problem.
2903	4	7	296	282	The guidance from this point onwards is very technical and not easily understandable and perhaps also not straightforward to apply, any simplification if possible (also in language) and further discussion on uncertainties would be appreciated.	Estonia Estonia	Noted	During the revision process we increased clarity where possible.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
								We agree that the methods are inconsistent with the other source categories, possibly with the exception of the IAV for

								There was a problem when converting the Word (and
						United States of		illustrator embedded figure) into PDF format. We have
3571	4	7	282	284	Figure 7.2, part of the decision tree graphic appears to be missing.	America	Accepted	corrected this problem.
3573	4	7	969	972	It is not clear why the full estimated emissions over a 100-year lifetime of a reservoir would be reported over a 20-year period. It would make far more sense to assume the emissions factors will be high for the first ~10 years, slightly lower for the next ~10 years, and then (once reported as "flooded land remaining flooded land") maintain a steady low level of emissions over the remaining lifetime of the reservoir.	United States of America	Rejected	Most of the total emissions attributable to the reservoir are emitted in the first years. For consistency with other land conversion, the 20 year threshold was used but also include the residual emission occurring after years.
3573	4	7	969		Nevertheless, the proposed methodology within the managed land proxy fails in properly quantifying the anthropogenic component of the GHG net emission in flooded land. Indeed, in absence of the water reservoir, the carbon components dissolved within the river water would naturally follow a path to GHG emissions (CO2 and CH4) that is different from the path they are following because of the reservoirs (more CH4 less CO2). Therefore, a proper quantification of the impact of the activity of flooding land should factor out such GHG emissions from organic matter in the water under a "natural" condition from that one occurring as consequence of the reservoir construction. Such symmetry in the method is needed because the IPCC methods do not estimate the GHG emissions from the organic matter in the water flowing in the river while the new method for the flooded land will do. This factoring out has nothing to do with the previous use of the land, since the factoring out, as per IPCC plenary decision, must be applied to the organic matter within the river's water, not to the emissions from land C pools, and it has to be applied under both conditions: lands previously managed or unmanged. It is recommended to revise accordingly the methodology.	Italy	Rejected	Both the 'stock change' method for mineral soils (in this guidance), and the 'flux based' methods for organic soils (2013 WS) account for the conversion of riverine carbon to CO2. In the stock change method this is implicit (all C lost from the soil is emitted as CO2, regardless of whether this occurs directly from the land surface or indirectly via the river network). In the 'flux-based method', additional organic carbon transferred from managed organic soils to the atmosphere is estimated and resulting CO2 emission is calculated. Construction of a reservoir may change the location at which carbon transformation (emission as CO2, burial as sedimentary C) takes place, but there is insufficient evidence to show that the construction of a reservoir changes the overall amount of CO2 emitted from riverine carbon in a consistent or quantifiable way. Therefore we have not been able to include guidance to estimate the effects of reservoir construction on the fate of carbon from upstream sources.

Commentio	volulile	Cliapter	rionnine	Tollile	Comments	Country	responses	Authors notes
3633	4	7	247	279	The factoring out approach proposed for flooded land on previous unmanaged land is inconsistent with the approach implemented for any other conversion of an unmanaged land to any other land use category. It is worth nothing that also other types of unamanged land are relevant sources of emissions and that their conversion is not factored out, e.g. conversion of natural peatlands to drained agricultural lands. If the proposed factoring out is accepted, it will require the redrafting of the managed land proxy approach, since reporting of conversion of unmanaged land to managed land will be based on a comparison of current emissions under management vs potential emissions under an unmanaged land scenario. As implemented in the current text, the factoring out approach seems designed for an accounting methodology of mitigation actions where the current GHG net emission is compared to a BAU GHG net emission, i.e. GHG net emission that would otherwise occur in a scenario where the current activity is not implemented, to account for its mitigation impact. However, such accounting is not within the scope of a national GHG inventory under the UNFCCC. Consequently, text in these rows must be deleted	Italy	Rejected	We agree that this method creates an inconsistency with other land uses, and also that there may be other relevant emissions that could be factored out with conversion to those categories. However, we have strengthened the justification for this approach in the Introductory section. Additionally, there was a mandate from the IPCC panel in TOR to include factoring out for this source, and only this source. Countries may ask for a redrafting of the managed land proxy if they decide this is needed. However, this method could be used in a restricted way or for accounting depending on decisions in the UNFCCC. We only dealing with estimation methods in this guidance. We complied with the scope in the TOR that the IPCC has made in this case, which did not include factoring out across all land uses and sources.

								We accept that it is good practice to report emissions using the managed land proxy, and have inserted text stating this guidance. We have also added text that addresses reporting of both Net and Total emissions as well as modifying the reporting tables. The following sentence has been added: "If a factoring out approach is applied, it is good practice to provide transparency by reporting both total and net emissions; otherwise the country should report the total emissions if net emissions are not estimated. Furthermore, if inventory compilers choose to factor out natural CH4 emissions from wetlands, it is also good practice to simultaneous factor out the loss of any natural CO2 sink in the that would otherwise have occurred if the land remained unmanaged " How this information is used for reporting by parties to the UNFCCC is a decision that will need to be made in the negotiations of the convention. We are only providing estimation methods and a
3645	4	7	660	672	according to comment on rows 247-279 delete this text	Italy	Rejected	framework for reporting in this guidance.

								The weight that is used is dependant on the production system-values in this table were derived from the information that is contained in the Annexes of the Chapter, Table 10A.1 to Table 10A.5. In the case of dairy cattle, live weights are used. In the case of other cattle, weighted live weights are used that are based on the relative proportion of different animal subcategories during annual production. As a general rule meat production systems, use the median weight of the animal during its growth to slaughter. Animals that are kept for the production of products (milk, eggs), draft or other uses of mature animals use live weight. The following line has been added: "The TAM should be consistent with median weight of the animal during its production stage. Typically, for animals used in meat production systems, this is the median weight of the animal during its growth period. Animals that are kept for the
					TAM: is it Typical animal mass at the middle of the growing period or		Accepted with	production of products (milk, eggs), draft or other uses would

								As mentioned in the text, bedding materials are used in solid manure management systems, when as a general rule methane emissions are lower than in liquid systems. Line 2624 refers specifically to large biomass inputs into biodigesters intended to increase methane production through the addition of material rich in carbon, and in the case of energy crops that could also be relatively rich in nitrogen.
245	4	10	1610	1611	As Nitrogen from bedding and additional N entering the system (Line 2624, co-digestates) can be accounted for, Carbon from bedding should be accounted for in C manure (VS).	France	Rejected	Further measurements of methane emissions on which methane emission factors are based, typically don't differentiate bedding from volatile solids, therefore the differentiation of bedding based methane and volatile solid based methane is not possible. For this reason, the carbon inputs from bedding to the methane production system are not explicitly quantified in the methodology.
247	4	10	1627	1627	equation 10.23: to calculate annual emission factor for livestock category the number of days should be a parameter and specific of the manure managment system and not considered to 365. For instance: how taking into account in CH4 emissions calculations of dairy cattles that spend 6 months in building and 6 months in pasture? or how to take into account of the periods of emptiness of buildings between the differents flocks for animal in confinments?	France	Rejected	The distribution of VS among different manure management systems is done through the AWMS fraction and not through the number of days of VS production. Likewise, though a barn may be empty it is assumed that the animal is still producing VS, whether in the barn or outside. If there are situations in which the animal may not be producing VS throughout the year, this should be taken into account in Equation 10.1.
249	4	10	1780	1789	examples of calculations with the different cited examples would have been apreciated.	France	Accepted with Modification	We have not provided specific examples in this case, but we have expanded the information that would need to be considered in carrying out these calculations. These type of calculations would not be considered as the prescribed Tier 2, but would be considered a country-specific application of the Tier 2 and therefore we wish to avoid confusion about what the default guidance is by providing a full example of the calculation.
								Composting systems are treated in the same way as manure heaps. The MCF applies to the full fraction of the annual VS that is tranferred to the composting system on an annual basis. The MCF is not differentiated based on the length of compost (retention time), as was done for the liquid systems because there is not evidence that methane emissions vary based on retention times in the same way liquid systems do. The deep bedding systems are differentiated based on their
251	4	10	1791	1792	Table 10.17: duration of storage should be indicated for composting and systems with litter	France	Rejected	lenght of storage, but only for less than one month and greater than one month.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
								The IPCC guidelines have been based on grouped systems since
								their initial implementation. To implement manure stages
								would be a significant deviation from the guidelines and would
								be beyond the scope of this refinement, which was to update
								emission factors and parameters, align methodolgies, but not
								develop entirely new methodologies, unless significant issues
								were identified with those as they stand. Grouping of systems
								was reviewed in earlier versions of the refinement; the
								collation of manure management systems and review of
								emission factors has been completed and reviewed in earlier
								versions of the refinement; there is no default emission factor
								for "deep bedding with additives" as additives comprise a very
								wide variety and act very differently; We were not able to
					Table 10.18: this table should be presented differently to facilitate the use			develop a default series of emission factors that are specific to frequency of manure removal based on the current available

					The Nitrogen from the bedding should be included in equation 10.25 as			It is correct that EF3 has been assessed for whole systems (i.e. manure excretion and bedding), but then the emission measured in these full systems were related to the original N excretion rates and it is rare that bedding N was included in the estimate of the emission factor. This means that the Efs include the effect of the bedding material, but are given in relation of animal N excretion; Bedding quantities are highly variable and difficult to assess. It was not possible to develop default values for bedding quantities due to the variability of bedding under different systems. Because default values could not be provided, it was judged that it was better not to include bedding in the calculations. It is however noted that this
267	4	10	1950	1950	EF3 has been assessed for the whole system ie excretion+litter.	France	Rejected	methodological change would be desirable in future updates.
269	4	10	1993	1993	equation 10.26: NbeddingMS should be accounted in this equation: N*awms (Nex + NbeddingMS) +Ncdg (same in eq 10.25) as fracgasms has been assessed on litter+excretion.	France	Rejected	It is the opinion of the panel, that since mineralization of nitrogen compounds in beddings occurs more slowly compared to manure and the concentration of ammonia fraction in organic beddings is negligible, both volatilization and leaching losses during storage of bedding are assumed to be zero. N in bedding is relevant to estimate the amount available for application - see Eqn 10.34. Further, due to the variability in the use and source of bedding it was not possible to develop default values to include in the equation and as a result it was preferred to not include it in the Tier 1 methodology.
271	4	10	2265		In equation 10.33C, calculation is as follow: (Bwfinal -Bwinitial)* Ngain(BWfinal), why not using Bwfinal*Ngain(Bwfinal)- Bwinitial*Ngain(Bwinitial) (solution 2). Moreover calculated N retention with Ngain provided in table 10.20B are very low for growing pigs compared to those calculated with more recent models like the model developed by Dourmad et al. and used in Dourmad et al. (2015) Underestimation of retention will lead to overstimation of excretion and emissions. Cf.: Dourmad J.Y. (coord.), Levasseur P.(coord.), Daumer M.,Hassouna M., Landrain B., Lemaire N., Loussouarn A., Salaün Y., Espagnol S., 2015.Évaluation des rejets d'azote, phosphore, potassium, cuivre et zinc des porcs. RMTElevages et Environnement, Paris, 26 pages.	France	Rejected	We have reviewed the Dourmad method and noted that it requires an additional parameter, muscle percentage, which has an influence on both the trend in N retention and the absolute amount. We feel this value could vary widely across the world and further could vary over the growth period. We further verified if the use of the Dourmad equation resulted in significant changes in total N excretion for a production cycle and noted that the values were within 5%. Therefore it is the panel's decision to maintain the values in the Table as is. The suggested equation also ignores the use of the subscript "i" which indicates the growth stage for which the Ngain values should be applied, therefore modifications to the equation are not required.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
273	4	10	2382	2382	Table 10.21: systems should be classified by manure magement step: building, storage, treatment. Durage of storage should be indicated and different EF should be proposed in function of the storage duration. This factor have an influence on the measured emissions level. In annex 10B, it is mentionned line 4032, given EF are expressed as kf of N2O-N kg of initial N-1. Initial N is not N excreted. Initial N is N coming to storage after building that means (Nexcreted -N emissions in buiding). These EF values have been reported in table 10.21 but not with the same unit (kg N2O-N.kg nitrogen excreted). This should be corrected as it can lead to a huge overestimation of emissions. All the values in table 10.21 should be checked considering that that kind of mistakes could have happened in other cells.	France	Rejected	The IPCC Tier 1 methodology does not distingush in the steps "housing" and "storage"; so initial N is N excreted, see the response to comment 253. The proposed change involves a modification that is beyond the scope of this refinement. Further, it is the panel's position that while this may be a desireable future improvement, with the current level of knowledge about emissions from steps and national information about manure management, this would be difficult to implement globally and would not necessarily result in an improvement of emission estimation accuracy.
275	4	10	2436	2436	equation 10.34: NbeddingMS should be reformulated regarding modifications suggested for equation 10.26 and 10.25	France	Rejected	N in bedding is relevant to estimate the amount available for application. Eqn 10.34 is correct. N in bedding material will flow directly to NMMS_avb (see comment 269). The approach is based on the assumption that the organic N in bedding will make its most significant contribution to emissions after field application.
277	4	10	2521	2521	Table 10.22: to avoid confusion in calculation % should be removed from the table. Fracgas-MS, Fracleach are divided /100 in equations 10.27 and 10.26. For storage and treatment Fracgas_MS should be corrected because they are not consistent with literature and not to Pardo el al 2015 because of a unit error. Emissions will be calculated regarding equations 10.26 and in this equation FracgasMS corresponds to the fraction of Nexc that volatises as NH3 and NOx. The value given in table 10.22 correspond to the fraction of incoming N (for storage) as given by pardo et al. 2015. The incoming N for storage is (Nexcreted -N losses in building). All the values in table 10.22 should be checked and corrected regarding this information to avoid huge overestimation and inconsistancy with NH3 inventories. To avoid this kind of mistake a mass balance approach even for tier 1 should be preferred. Applying the volatilisation coefficient directly to N exc for storage and treatment is not relevant because it means that we do not consider what occured in the building before the outdoor storage. Usually EF assessment is not express in function of Nexc, that means the conversion of the EF /kg of Nexc required some data thant are not directly available in the paper.	France	Accepted	Table 10.22. "%" have been removed from the table and equations have been ammeded accordingly. FracGas_MS considered in IPCC (2019) includes N losses from housing and storage all together. Values have been taken from current EMEP/CORINAIR (2016) for categories present in EMEP/CORINAIR (2016). EMEP EF values, which are expressed per TAN excreted have been re-calculated to be expressed as a funtion of total N considering the mass balance flow between the different manure management phases prior to manure application (housing, yards, storage). For other categories not present in EMEP we used Pardo et al. (2015) relative EF's differences between conventional solidwaste against composting, etc. as the basis (for the storage phase) to estimate EFs for the manure management phases prior to manure application (Includes housing). We assumed no N2O or N2 losses prior to storage. Some text has been added in the solid manure Annex to clarify this.
2//	4	10	2521	2521	Figure 10.5: Nbedding has to be moved at the same level than N ex N	iriance	Accepted	The equations were checked and corrected, but Nbedding was maintained in the same position based on the response to

1705	4	10	1592	1593	Table 10.14. Since the EFs are given in g CH4 PER kg VS, we see the following logical problem. For example, we do not understand, why a slurry system that stores manure from "high productivity systems" should feature an EF that is nearly twice as high as the EF for the same slurry system storing manure from "low productivity systems"? Differences in VS excretion per animal might occur dependent on high or low productivity systems, but we feel that EFs of identical manure storage systems related to VS (in the same climate zone) should be identical.	Germany	Rejected	For the most part, these emission factors have been developed directly from the information in the 2006 guidelines, the B ₀ values for developing countries were used for the low productivity systems and the developed countries for the high productivity systems. The B0 value drives these differences. In cases where we did not find information that could effectively confirm or reject the values published in the 2006 guidelines we maintained the existing values. It is the hope of the hope of the panel that the presentation of Tier 1 emission factors on a g CH4 per kg VS basis will encourage researchers will begin to publish comparative measurements based on VS that will lead to significant improvements when there is an opportunity to revise the values again.
1703	4	10	1592	1595	to v3 (iii the same climate zone) should be identical.	Germany	Rejected	levise the values again.
1707	4	10	1742		From our point of view, it would provide a more consistent approach to keep animal-specific default Bo values for all MM systems. The animal-independent value suggested for the management system "grazing" does not follow the current systematic approach (animal-specific Bo, manure management system specific MCF) in the guidelines and seems like a step backwards.	Germany	Rejected	The current manure management methodology is based on a model that was developed for anaerobic digestion. It is the position of the panel that the concept of using an anaerobic digestion model is probably not appropriate for grazing situations, where warm temperatures can dry dung pats and wet conditions can dilute the dung. Even so, we calculated MCF based on the animal-specific B0 values. The current results are based on a compilation of experimental results and the results showed no statistical difference between animal categories. A similar non-significant result was found for cattle and sheep EF values. On this basis, it was decided that a single value for EF and for B0 was appropriate.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
								The N intake is not in fact per year, it is per day and therefore the 365 is required to be consisten tiwh the application of N excretion in the emission factor equations. We have corrected the unit for intake.
					Please correct Equation 10.31: If both terms Nex(t) and Nintake(t) are already normalised over one ("kgN animal-1 year-1"), the multiplication		Accepted with	This comment has however identified an important inconsistency that was futher resolved in this revision. Equations 10.33 to 10.33E all calculated N retention in as a quantity and not a fraction (note that this issue existed already in the IPCC 2006 Guidelines). Therefore, further calculations were required in order to calculate an N retention fraction such as is presented in Table 10.20 and would be applicable in Equation 10.31. We have resolved this issue by including an additional equation, Equation 10.31A in which the N excretion is calculated based on the difference between intake and retention. Further, in the case of Swine, instructions are provided to calculate daily N retention to make these calculations consistent with equations 10.31, 10.31A and 10.32,10.32A

1513	4	11	General con	General con	The proposal from the previous version of distinguishing EFs from synthetic fertilizer and other inputs has been maintained. The requested clarification from the previous review comments on differentiating EFs from organic amendments has not been included. In reality much of the manures (including slurries and digested manures) that are used in intensive agriculture have high contents of mineral N. The proposed EFs for wet climates provided very large differences (0.006 for other N inputs and 0.016 for synthetic fertilizers). In reality there will for liquid based manures mostly be very little difference between EFs for these manures. This is a problem for using these EFs in wet climates with intensive agriculture.	FU	Accepted with	Thank you for this important comment. The authors acknowledge the potential difference in EF between liquid and solid forms of organic fertilisers. However, there is insufficient data to disaggregate the EF1 into liquid manure and solid/slurry manure. This would therefore require development of country-specific Tier 2 values. The text was amended before Table 11.1.

1729	4	11	1236		sheep and clarify that there are not disaggregated EF3PRP values for sheep displayed in Table 11.1 anymore.	Germany	Accepted	and that there are no disaggregated sheep excreta EF3PRP values.
1787	4	11	363		It seems that the unit of AGR (T) is not "kg d.m. ha-1" but "kg d.m.". In addition, the equation (AGR(T) = Crop(T)* Slope(T) + (Intercept(T)*1000)) in Table 11.2 needs to be revised by "AGR(T) = Crop(T)* Slope(T) + (Intercept(T)*1000)*Area(T)*Fracnew(T)" and the unit of AGR(T) needs to be "kg d.m.". We suggest the unit and equation be checked and revised, if necessary.	Japan	Accepted with Modification	The unit was corrected to kg d.m. y-1 . However, given changes to estimate aboveground residue dry matter in Equation 11.6 based comment 989, it was not necessary to change the calculation in Table 11.2 to estimate kg dm. The multiplier of 1000 in the equation given in Table 11.2 was removed following these checks because it was not needed.
1789	4	11	371	271	It seems that the unit of BGR (T) is not "kg d.m. ha-1" but "kg d.m.". The unit be checked and revised, as appropriate.	Japan	Accepted	The unit for BGR (T) was corrected as kg d.m. yr-1.
2775	4	11			The phrase suggests that the disaggregation can be performed when either climatic or fertilizer type information is available. Based on the Table 11.1 this could pose ambiguity when one part of the information is available. For example, if they know all of the N applied is organic without the climate information, disaggregated values may not be useful. Thus, the statement should say "activity data by climate and fertilizer type".	Canada	Accepted	Thank you for the suggestion, this is correct and the text was amended as suggested.
2777	4	11	1217		The uncertain range is extremely small for this parameter. I believe that the use of bootstrapping for this is underestimating the uncertainty. Bootstrapping attempts to reproduce the standard error of the population. As note in Volume 1 Chapter 3 on uncertainty, there are circumstances when the standard error should be used and there are times when the standard deviation should be used to define the uncertain bounds. In this case, it should be the standard deviation as this is a simple sample of the emission factors. The use of bootstrapping and therefore the development of standard error estimate underestimates the uncertainty as it would apply to a country that is applying that emission factor in their inventory. For the other EFs, though the range is not nearly as small as EF3, it should be clarified how the uncertain range were derived and assure that the approach used is consistent with the guidance in Volume 1 Chapter 3.	Canada	Accepted	For consistency with guidance in Vol. 1 Chapter 3, the confidence interval of the aggregated EF1 was recomputed using the standard deviation of the mean. This led to a slighly larger confidence interval. Formerly the low and high uncertainty values had been assigned the 2.5th and 97.5th percentiles of the dataset generated by bootstrapping; they were not based on the standard error. The updated confidence interval of [0.001; 0.018] seems reasonable in comparison with the uncertainty of [0.003; 0.03] in the 2006 guidelines, given the much larger dataset used for producing the EF1. The uncertainty ranges for EF3 have been revised by adopting the method outlined in Vol1 Chapter 3. This has resulted in a larger range of EF3 values that are more representative of the potential range of mean values that could be determined by individual countries.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
335	4	12		276	We welcome the use of the wording "assumption of steady-state HWP pool" which is a more appropriate and less confusing than the previous wording "instant oxidation assumption" used in previous IPCC guidance (see lines 513-515). We suggest that the differences between the two be briefly explained here (with a reference to section 12.4.1.2 lines 505-522.) and to write that the new wording should be preferred now. We suggest improving the clarity of this sentence by explicitly giving the	France	Accepted with Modification	We have included a brief clarification in a footnote and have added to the discussion in Section 12.4.1.2. We have modified the text discussing Equation 12.5 in the light
337	4	12	662	663	two components of Equation 12.5 to which reference is made.	France	Accepted	of the comment. This includes explaining what the two components are, immediately after mentioning them.
339		12		983	Please consider the opportunity to add some further developments on the consistency to be ensured between country-specific emission factors for HWPs and other parameters used in Tier 2 methods to estimate aboveground biomasses (see section 2.3.1.3 of Chapter 2, Volume 4). In particular, it could be expected to some extent that consistency should be ensured regarding the use of wood densities to estimate change in aboveground biomass carbon stock and HWPs carbon stock.		Rejected	Emission factors (i.e. half-life or service life) information on the duration of the use of wood in use in relevant markets is independent from any information relevant for estimating above ground biomass and vice versa. Wood density of processed wood (i.e. wood commodities as covered by statistics) on the other hand (relating to activity data not emission factors) do NOT relate to standing timber /above ground biomass in forests — especially not in the case of composites, such as wood-based panels (consisting of different feedstocks incl. glue and additives).
341	4	12		992	It may seem unappropriate to base IPCC guidelines on a private and fee-based access standard (ISO). Would it be possible to consider an open and free-access alternative, ideally from UN statistics or database?	France	Rejected	To our understanding, there are no widely-applicable alternative sources of relevant information, presented according to an internationally consistent defined standard. The international standards provided by ISO are an accepted source of information which has already been referred to in previous IPCC guidance (IPCC 2006 GL Vol 2 or KP Supplement). To our understanding, the development of alternative methods would also incur costs and the deployment of resources.
343	4	12		1237	Table 12.5 is useful and should be kept. Would it be possible to specify the consequences in terms of double counting and omission resulting from the use of different approaches by different countries? (see Lines 265-269).		Rejected	It would be inappropriate for us to provide the requested information because this could be interpreted as the guidance "taking a view" on the relative merits of selecting amongst the various approaches, which is still under discussion by SBSTA, hence being prescriptive about the choice of approach. However, we would note that the information in Table 12.5 could be rearranged easily by a reader, to find out the requested information.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
345		12		1552	Specify that 44/12 is the fraction resulting from the molar masses of CO2 and C, and useful to switch from a measurement in tC to a measurement in teqCO2.	France	Accepted with Modification	A cross-reference has been added to "Vol. 4 Ch. 2 Section 2.2.3". The application of this conversion factor is not unique to HWP and relevant text is included in Chapter 2 of the Volume 4, IPCC 2006 GL: "The conversion to CO2 from C, is based on the ratio of molecular weights (44/12). The change of sign (-) is due to the convention that increases in C stocks, i.e. positive (+) stock changes, represent a removal (or 'negative' emission) from the atmosphere, while decreases in C stocks, i.e. negative (-) stock changes, represent a positive emission to the atmosphere."
					Chapter 12 considers only semi-finished wood products (sawnwood, wood-based panels and paper& paperboard) as Harvested Wood Products . However, Roundwood is often used in some countries for constriction of buildings, private houses and that is the best option for long-lived carbon storage in HWPs. Unfortunately a such option is not considered within the chapter 12 at all. Please, add some guidance of estimation of such HWPs, how to avoid double-counting etc.		Accepted with Modification	The direct use of roundwood or logs in end-uses is covered by the commodity class "other industrial roundwood" as part of "industrial roundwood". The use of these datasets is covered by Tier 3 methods as explained in Section 12.4.1.1. Please note that the commodity class "industrial roundwood" excludes e.g. telephone poles; the use of such datasets representing enduses requires country-specific information on end-uses and methods, i.e. not to be combined with default FOD-function). We have amended Section 12.4.1.1 by adding the definition of "other industrial roundwood" to the list of definitions provided. We have also referred to "roundwood used directly in the construction of buildings" in the preceding discussion of the difficulties in using data on other industrial roundwood in conjunction with Tier 1 and Tier 2 methods.
497	4	12	1	1719	Would be useful to develop excel calculation sheet for HWPs as well as it is done e.g. for Tier 2 Steady State Method	Russian Federation	Rejected	We agree that it would be useful to provide standard calculation worksheets. However, experience from developing the 2006 GL suggests that is a major undertaking and unfortunately there was insufficient capacity and time for this work as part of this refinement. Please note that the authors provide a calculation example on how to implement the FOD default method (i.e. Equations 12.2 and 12.4) in Box 12.1.
499	4	12	1	1719	There is no possibilities for "non-counting of emissions and removals" with various Approaches. Only double-counting is possible. Please, delete "non-counting".	Russian Federation	Rejected	The text referred to in the comment is explaining a general principle about the important purpose behind the definition of approaches. It does not offer any view on whether the available defined approaches actually lead to double-counting or non-counting of emissions. The text simply explains that one of the purposes of defining approaches is to avoid these sorts of outcomes.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
2795		12	706	200	Line 100 states that this chapter maintains the existing approaches covered in the 2006 IPCC Guidelines: in doing so, this chapter should seek to build on the existing approved guidance in the 2006 IPCC Guidelines and should be careful to not ignore or misrepresent that guidance. The 2006 GL includes the simple decay approach, and this approach should be represented accurately. A more accurate text is "Approaches identified in the 2006 IPCC Guidelines are the 'stock-change', 'production', 'atmospheric-flow' and 'simple decay' approaches. As explained below, these approaches have differences in terms of their conceptual frameworks and the system boundaries employed for calculations (Section 12.2)."	Canada	Accepted with Modification	The text has been amended to read: "The 2006 IPCC Guidelines considered four approaches known as the 'stock-change', 'production' 'atmospheric-flow' and 'simple-decay' approaches".
2785	4	12	206	208	Even though the 'simple decay' approach is similar to the 'production'	Canada	Accepted with	The text in the relevant section and also in Annex 12.A has
					approach in term of the system boundary, there is a fundamental difference clearly noted in the 2006 IPCC Guidelines that should be noted as well in this 2019 refinement. This is the difference as noted in the 2006 guidelines: "The Simple Decay Approach differs from Production Approach in that HWP pool is considered to be related to activities in the forest and hence does not assume instant oxidation of wood in the year of harvest.". This text should be maintained in this refinement and should be added to the text in this paragraph.		Modification	been amended extensively following very careful review and reconsideration of this subject. The 'simple-decay' approach is discussed more fully, and the point (and spirit) requested to be addressed in this comment has been covered, although the wording is different, mainly for the sake of clarity.
2787	4	12	206	215	, , ,	Canada		
					This text misrepresents the 2006 IPCC Guidelines on the subject of the simple decay approach, and our previous comments on this point have not been adequately addressed. The 2006 GL clearly states that the simple decay approach does not have the same conceptual framework as the production approach, in the sense that "conceptual framework" is described in section 12.3.1 as either 1) changes in carbon stocks within defined HWP pools or 2) actual CO2 fluxes to and from the atmosphere. Specifically, the 2006 GL (volume 4, page 12.30) states: "The Simple Decay Approach differs from Production Approach in that HWP pool is considered to be related to activities in the forest and hence does not assume instant oxidation of wood in the year of harvest." The text should be changed to read: "In this guidance, the 'simple decay' approach is treated as having the same system boundary as the production approach but a conceptual framework that focusses on quantifying actual CO2 fluxes, applied in conjunction with a country-specific calculation method. Further discussion of country-specific methods is presented in Section 12.4.4 on Tier 3 methods. Detailed information about the 'stock-change', 'production' and 'atmospheric-flow' approaches are provided in Annex 12.A."		Accepted with Modification	The text in the relevant section and also in Annex 12.A has been amended extensively following very careful review and reconsideration of this subject. The 'simple-decay' approach is discussed more fully, and the point (and spirit) requested to be addressed in this comment has been covered, although the wording is different, mainly for the sake of clarity.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
					Line 100 states that this chapter maintains the existing approaches covered in the 2006 IPCC Guidelines: this chapter should seek to build on the existing approved guidance in the 2006 IPCC Guidelines and should be careful to not ignore or misrepresent that guidance. The 2006 GL includes the simple decay approach, and this approach should be represented accurately. It is incorrect to say that specific guidance on implementation of the simple decay approach was not given in the 2006 IPCC Guidelines. Guidance was provided on the approach in the 2006 GL: see volume 4, page 12.30 and page 12.24 which explain which HWP variable to use for the approach, with the calculation of the variable explained earlier in the chapter. Replace this paragraph with: "The 2006 IPCC Guidelines defined how to calculate emissions and removals of CO2 associated with HWP for the 'stock-change' approach, 'production' approach, 'atmospheric flow' approach and 'simple decay' approach. A detailed supporting description is provided in this annex for the first three. The 'simple-decay' approach is also maintained in this updated guidance by recognizing it as having a system boundary like that of the production approach but using a conceptual framework based on identifying and quantifying actual CO2 fluxes to the atmosphere, in combination with a specific (essentially Tier 3) calculation method. The general guidance on Tier 3 methods in the main chapter (Section 12.4.4) may be referred to."		Accepted with Modification	The text in Annex 12.A has been amended extensively following very careful review and reconsideration of this subject. The 'simple-decay' approach is discussed more fully, and the point (and spirit) requested to be addressed in this comment has been covered, although the wording is different, mainly for the sake of clarity.

653	4	Cover page	1	_	General editorial comment on all chapters in Volume 4: when "it is good practice" is stated sometimes it is italicised and sometimes not, so please check for consistency throughout volume. We do find it useful to italicise this material.	New Zealand	Noted	
103	4	General			Comment on Volume 4, AFOLU: We have expressed before our concerns with respect to the references to the 2013 supplement on wetlands in relation to organic soils. As Government department and as inventory compilers, we want this 2019 refinement to be adopted by the COP and/or CMA as mandatory basis for the elaboration of GHG inventories under the UNFCCC. 2013 supplement is only for voluntary use, governments didn't manage to adopt it as mandatory for the elaboration of GHG inventories under the Convention, and we fear that the references to the supplement in the refinement could jeopardize the adoption of the 2019 refinement under UNFCCC as methodological guidance to be used for inventories in the future. Therefore, we suggest to delete those references, or replace every reference with a neutral language: "2006 GLs on organic soils were complemented by 2013 supplement on Wetlands. This document does not preempt which of these guidance are to be used."	Spain	Rejected	Organic soils and wetlands in general were out of scope for refinement, with the exception of flooded lands. The 2013 Wetlands Supplement provides the latest guidance associated with wetlands, which has been reviewed and approved by the IPCC plenary. The decision about using this guidance for national inventory reporting is made in the UNFCCC. This refinement just points to the latest guidance on wetlands, which has been approved by the IPCC process and is available for reference.
67		General Comment			The IPCC guidance has to be developed in a simplified way to enable all countries to estimate their corresponding ghg emissions taking into account shortage of data and national capacities and expertise Meanwhile, the way the guidelines is developed is somehow written in difficult way to be understandable in some parts (particularly AFOLU), so it needs to be taken into account more simplifying the GL language in future refinements	Egypt	Noted	The acttion is outside the scope of the agreed refinements listed in the ToR. To be further considered by IPCC

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
1227	5	2		294	(All Tables) Recommend reviewing data relating to Australia, including zero waste composted and composition of MSW containing zero plastic and metals. Would suggest that both AU and NZ data is reviewed. The data presented for waste generation in Australia and New Zealand are not accurate. Better numbers, at least for Australia (which is 80% of Australia and New Zealand) are: MSW generation 0.57 t/person; fraction open dumped 0; fraction to landfill 0.58; fraction incinerated 0; fraction composted 0.21; fraction to other 0.21.	Australia	Rejected	We thank for your comments. Table 2A.1 showed the waste generation and management data in the year 2000 (from 2006 IPCC Guidelines) and in the year 2010. The values are in the same year for every countries with the aims to be consistent and comparable among countries and regions. We have checked the reference of Australia National Waste report 2016, table 12 (provided for comment 1229) and found that the value in 2010-2011 is 0.61 t/capita which is in line with our proposal in the refinement. In addition, National Greenhouse and Energy reporting (measurement) Determination was compiled on 1 July 2018 and registered on 25 July 2018 which is after the cut off date (25 June 2018).
					(All tables) Decreased associative data relative to Australia for insut			Defending to manifold unforces. National Wests Deposit
1229	5	2		294	(All tables) Recommend considering data relating to Australia for inert waste fractions that can be derived from the national waste report workbook ('other national data'): metals 0.03; plastics 0.12; glass 0.04.	Australia	Accepted with modification	Referring to provided reference - National Waste Report workbook on 'other national data' - waste composition of Australia in Table @2A.2 has been changed.
1967	5	2	288	290	MSW Generation and Management Data (Table 2A1) presented for Uruguay is not correct. The correct values are (SOURCE: MVOTMA): Generation rate 0,35 ton/cap.year; MSW disposed in SWDS 82 %; Open dump: 0%; Other management:18 % (includes compost, recycling and others)	Uruguay	Rejected	Reference provided is of April 2019 which is after the literature cut off date of 25 June 2018 for the 2019 Refinement
157	5	3	484	484	A new type of SWDS has been added in the 2019 Refinement: active-aeration. The practice of implementation of active aeration of solid waste disposal site (SWDS) is very limited (Appendix 3A.2, chapter 3, Volume 5). On the other hand, the case of "bioreactors" is still not considered although it may correspond to an important part of SWDS in some Parties, such as France.	France	Noted	No action can be taken because comment is out of scope of 2019 Refinement.
1215	5	3	348	377	Recommend incorporating two papers published since the second review of the Guidelines. The papers have suggested new DOCf factors for wood and wood products.	Australia	Rejected	We thank for the additional reference suggestion. However, this paper is published on 15 December 2018 which is after the literature cut off date of 25 June 2018 for the IPCC 2019 Refinement. Therefore, it is unfortunate that we can not combine this reference in the IPCC 2019 Refinement.
					Recommend including two additional references: Less decomposable wastes include tree branches and harvested wood products such as sawn			
1217	5	3	355	356	and engineered wood materials.	Australia	Noted	Reference has already been in the FD.
1219	5	3	360	361	Recommend including one additional reference: The biodegradation yield of the waste component under anaerobic condition varies greatly depending on the material type, ranging from minimal yield for wood and wood products	Australia	Accepted	Reference has been added.
1221	5	3	362	363	Recommend including one additional reference: Meanwhile, biogenic carbon conversion of paper products varies greatly (21% to 96%) depending on the type of paper.	Australia	Rejected	We thank for the additional reference suggestion. However, this paper is published on 15 December 2018 which is after the literature cut off date of 25 June 2018 for the IPCC 2019 RefinementTherefore, it is unfortunate that we can not combine this reference in the IPCC 2019 Refinement.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
529	5	6	419	442	It should be noted, that despite correct, the Equation 6.1 (updated) can be confusing then calculating, because in proposed steps this equation is more suitable to estimate only emissions from treated wastewater, not from discharge pathways. It is especially evident as in the Equation 6.1A(new) there are two special components to calculate emissions from wastewater effluent discharged to environments. Additional explanations or text reorganization may be useful.).	Russian Federation	Accepted	The fact that CH ₄ emissions from both discharge pathways and treatment systems have to be considered in the inventory has been emphasised in the document. In particular a list of treatment systems and discharge pathways has been added in the text before Equation 6.1 (UPDATE).
531	5	6	423	423	It can be useful to add explanation about checking in calculations that TOW input (both as a whole and at the every one considered wastewater treatment system) should be consistent across the wastewater pathways and at the end with TOW output to the environments taking into account organics removal including loss to sludge and biological decomposition.	Russian Federation	Rejected	TOW input and TOW output do not have to be equal, and in fact won't be equal due to conversion of TOW into $\mathrm{CH_4}$ and into $\mathrm{CO_2}$ and other NMVOC. The information on how to estimate TOW is provided in Section 6.2.2.3 - Choice of Activity Data, including an example of application.
533	5	6	440	444	Units for CH4 emissions in the Equation 6.1A(new) (and others equations) in kg can be a reason for mistakes, because the final emissions data for NIR should be in Gg (kilotons). Please, check these units again.	Russian Federation	Accepted	Equation 6.1A(New) has been modified to result in final emissions in Gg.
535	5	6	440	455	There are two special components to calculate emissions from wastewater effluent discharged to aquatic environments in the Equation 6.1A(new). It is noted, that wastewater effluent discharged to (wet) soil is excluded from the equation despite the same origin and produced methane emissions (see Table 6.3 (updated)). Please, add such emissions as additional coponent of the equation or explain why it is omitted.	Russian Federation	Accepted with modification	A simpler version of Equation 6.1A (NEW) is now proposed which is simply the sum of methane emissons from all discharge pathways and treatment systems. Some additional discussion has been added to the text before Equation 6.1 (updated) to note that this equation has to be applied to all types of discharge (discharge to reservoirs, lakes and estuaries; discharge other than to reservoirs, lakes and estuaries; and discharge to sewers) which includes discharge of treated and discharge of untreated wastewater.
537	5	6	440	455	If TOWEFFtreat is only for discharged treated wastewater effluent than untreated wastewater effluent is missed despite it also can be discard to different environment (as %Tiers 1 and 1A). Please consider the possibility to add untreated wastewater effluent or clearly explain how it is included.	Russian Federation	Accepted with modification	Untreated wastewater effluent should use TOW, since no removal of organics happens before discharge. We have added an explanation in Equation 6.3A to clarify this.
539	5	6	440	455	The components %Tier 1 and 1A in the Equation 6.1A(new) can be confused with the component FWTk from the Equation 6.3D(new). Also it is a source of mistakes if experts already have used FWTk for wastewater treatments systems, differentiated by discharged wasterwater effluents receiver types. Please add some explanations and quidance.	Russian Federation	Accepted with modification	In response to comments, the components of % Tier 1 and 1A have been removed.
541	5	6	440	455	Please consider reorganizing Equation 6.1A(new), for example, as a sum of emissions from water discharge to the environment, untreated system, and treated system (according to the Table 6.3(updated)) with additional equation especially for emissions from discharged wastewater effluents.	Russian Federation	Rejected	Please see response to comment 535. There is no reason to propose two separate equations for dischage pathways and for treatment systems as the equation 6.1 (updated) can be applied to both cases and, moreover, there is no need to report separately discharge and treatment emissions.

557	5	6	608	610		Russian Federation	Accepted	The text has been updated.

CommentID Volume Chapter Fromline Toline Comments	BOD, or biochemical oxygen demand, is not the mass of organic constituents in the sludge. Rather it is a value that describes the
In the text and in the Table 6.6A(new) there are k more than 1 (more than 1 kg of BOD in one kg of how it is possible. Please make an additional verif	strength of the waste (literally by estimating the amount of oxygen microorganisms require to metabolise the organic material). Essentially it is a proxy indicator of the quality (or organic content) of the waste, but it is not a direct mass measurement of the organic content. Just as the mass of oxygen in carbon dioxide is greater than the mass of carbon, it is feasible for the BOD of a carbon-containing molecule to exceed 1 when the molecule is metabolised to carbon dioxide. The Krem values indicate how measured BOD changes for a tonne of sludge during different levels of treatment. So a value of 0.5 means that the value of the BOD measurement of the treated waste has reduced by 0.5 kg of oxygen consumed (which is a surrogate for organic content) compared to the untreated waste. Data usually available for inventory compilers concerning sludge removed is usually expressed in mass. Equation 6.3B (new) is provided in order to convert into kg of BOD removed as sludge at all stages of the process (Saerobic)
559 5 6 621 629 explanation.	Russian Federation Rejected as necessary for the application of Equation 6.1 (updated).

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
					Discharge emissions should not be limited to primary treated discharges.			
					Evidently, discharge emissions should be calculated also from secondary			
1139	5	6	289	289	or tertiary treated wastewaters (Equation 6.3D and Table 6.6B).	Finland	Accepted	The word "primary" has been deleted as suggested.
								The reference to Figure 6.1 is correct, as this figure shows the
								potential discharge pathways and treatment systems that
1141	5	6	720	720	Figure 6.1 should be Figure 6.3	Finland	Rejected	should be considered in the inventory.
					Chapter 6.2.3 Industrial wastewater is incomplete. Equation 6.6 does not			Equation 6.6 is located in Section 6.2.3.3 of the 2006 IPCC
					exist. Also, there is no equations for wastewater discharge (Figure 6.3 and			Guidelines and is not refined as part of this document.
					Table 6.8 indicate that there should be equations). The Worksheets for			Inventory compilers should refer to the original 2006 GL for
1143	5	6	718	719	industrial wastewater are incomplete, also. Please correct.	Finland	Rejected	these unrefined sections of the chapter.
1143	3	0	710	719	industrial wastewater are incomplete, also, Flease correct.	illialiu	Rejected	these unrenned sections of the chapter.
								We replaced "most freshwaters are highly supersaturated" with
								"surface marine waters are typically supersaturated (Conrad
					Please add seas and oceans to the text (line 298) and to Tables 6.3 and			and Seiler, 1988; Ward et al, 1987) and freshwaters highly
1145	5	6	298	298	6.8.	Finland	Accepted	supersaturated with CH4 (Stanley et al, 2016)".
<u>1147</u> 1149	5	6	902	902	There is only one default EF for centralised, aerobic treatment plant. Is this valid for all those plants (in second-order draft there were two default values)? Please check and justify. Please add a default EF for industrial wastewater plants or indicate what to use in case there is no default EF to give.	Finland	Rejected Accepted	We considered the development of two EFs for BNR and non-BNR processes, as proposed in the Second-Order Draft. However, following comments received from reviewers, we conducted additional statistical analysis of the data and found that there is no significant difference in EFs of BNR and non-BNR systems. Therefore, only one EF for all centralised, aerobic treatment plants has been proposed in the Final-Order Draft. Please see Annex 6A.5 for more details on the analysis. A reference to Table 6.8A (New) has been added to the explanation of EF.
1151	5	6	1002	1002	domestic should be industrial.	Finland	Accepted	explanation of Et.
1313	5	6	490	490	Dishcarged BOD values are even lower for "new" processes such as the MBR process. It usually generates discharged concentrations of BOD < 2 mg/L. This is also common in well managed conventional activated sludge processes. A comment stating that really low BOD values (<2 mg/L) are not that uncommon in well managed modern plants would seem to be needed here.	Sweden	Rejected	We used the word "typically" which is appropriate for a global guideline. Many plants do better, but it does not appear necessary to make the text more extensive.
					he numbering of the steps is confusing: should all steps 1, 1A AND 1B be			
					conducted, or can 1A and/or 1B be skipped if step 1 is conducted? It is			
					difficult to distinguish here the difference between a step with only a			
					number (eg. Step 1) and a step with both a number and a letter (eg. 1A).			To improve clarity, the steps have been renumbered to only be
1315	5	6	371	371	This would be good to clarify.	Sweden	Accepted	numbers with no letters.
					Please specify if NREM always be taken from Table 6.17, even if more			
1317	5	6	976	976	country specific data is available?	Sweden	Rejected	See response to comment 1391.
					Some of the values in the table 6.5 are close to 20 years old. An update			No action can be taken because comment is out of scope of
1319	5	6	612	612	would seem to be called for, with more up-dated figures.	Sweden	Noted	2019 Refinement.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
	Volume General	Chapter	Fromline	Toline	The Chinese government thanks the members of the Bureau, the lead authors and the Technical Support Unit (TSU) of the Intergovernmental Panel on Climate Change (IPCC) for 2019 Refinement to the 2006 IPCC Guidelines for National Greenhouse Gas Inventories (2019 Refinement) for their hard work in preparing this methodology report. In order to have a more science-based, comprehensive and balanced IPCC assessment report with fully reasonable and actionable findings when applied, Chinese government has made the following comments on this draft in the hope that they will be adopted in its revision process. 1. On accounting fugitive emissions from coal exploration. As a methodology report that will be widely used, the accounting method described therein should be rigorously science-based, sufficiently informed with reference and highly actionable. There being few studies on how to account for fugitive emissions from coal exploration, there is a clear lack of literature support in this connection, which leads to difficulties in data availability. Therefore, it is suggested to relocate the text on the accounting of fugitive emissions from coal exploration in Section 4.1.6, Chapter 4, Volume 2 to the annex of this Volume. 2. On the formulation and presentation of formulas in the report. As an important part of the accounting method, the accuracy of the formulas is particularly important. Some of the formulas in the report are inconsistent in quotation and incorrect in dimension as found, for example, in Lines 259-402, Chapter 4, Volume 1; lines 2891-2892, in Chapter 4, Volume 2; Lines 369-380, Chapter 4, Volume 3; Line 1108, Chapter 5, Volume 4;	Country	Responses Accepted with modification	For 1), the comment has been accepted. For 2), the comment has been accepted. Errors have been corrected where they were found. For 3), citation errors, typographical or grammatical errors will be corrected during the final copyedit before the publication of this report. Cosmetic improvements will be also made during the final copyedit, including improvement of presentation of figures/pictures. Substantial inconsistencies (not just editorial or typographical), where found, have been corrected. For 4), the comment has been noted. Consideration of different national conditions is already addressed by the tiered approach and decision trees. About provision of new/updated default emission factors, developing country data/EFs as well are already covered, for example, for coal, charcoal and biochar in Energy Sector (Vol.2).
1285	General	General			Lines 337, Chapter 6, Volume 4; Lines 349-381, Chapter 11, Volume 4. It is The methodology for rice cultivation and agricultural soil is very well written by the various experts. I wish some publications from India specific work was added to nitrous oxide from agricultural soils. There is no literature at all for emission coefficients from Indian conditions in the methodology chapters.	China	Noted	The authors did not find published studies specific to the Indian conditions in the literature review, and no specific articles were brought to their attention during the reviews. However, inventory compilers can use country-specific data when developing Tier 2 or 3 methods.
1379	General	General			We appreciate the hard work of the authors, and others who have	IIIuia	Noted	Noted with thanks.
					contributed to the preparation of the report.	Sweden		
1965	General	General	all	all	The approach to generating a standalone document to be used in conjunction with the existing 2006 GLS is very confusing and will make the job of compilers, especially inexperienced compilers in countries that are not Annex 1 countries, extremely difficult and inefficient. It would be far preferable for the Refinement and 2006 GLs in future to be integrated into ONE set of inventory compilation documents. Compilers should not need to have two sets of complex technical materials to work with, and have to constantly cross-reference using mapping tables and hints throughout the Refinement text - it will lead to inconsistencies in application of the guidelines, reducing the quality of the dataset available to the UNFCCC and IPCC, and also be resource-intensive to work in that manner.	United Kingdom (of Great Britain and Northern Ireland)	Noted	IPCC decided to prepare a "2019 Refinement to the 2006 IPCC Guidelines for National GHG Inventories" (2019 Refinement), which will not replace the 2006 IPCC Guidelines; it will be used in conjunction with the 2006 IPCC Guidelines. Consolidating all methodological guidance into a single report would require a new IPCC decision, subject to be discussed in the IPCC plenary.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
2833	General				It is difficult to understand the meaning of many sentences throughout the chapter because the English grammar and style still need to be fixed/refined (i.e. lines 206-207 should be "The material can be used both by countries establishing a data collection strategy for the first time and by countries"; lines 209-211 should be "the progress of emission trading programmes or climate change policies have the potential"). (Disregard this comment if it's planned to have another edit to fix the English).	Belgium	Accepted with modification	The text has been revised and English checked. Specifically, for the indicated lines 206-207, the text does not seem to have any problem and has been mantained the same. The text in lines 209-211 (which are to be read 940-941) has been slightly changed to increase readability.
2883	General	General			We thank the authors for their hard work on providing the refinements to		Noted	Noted with thanks.
					the 2006 IPCC Guidelines for National GHG Inventories.			
						Estonia		
2949	General	General			The inclusion of text from the original 2006 Guidelines (in grey in the draft Refinement) appears to be inconsistent. Sometimes there are entire sections of grey text, with a minor phrase or one to two new paragraphs (in white) included. Sometimes there is no grey text; it is difficult to understand in these cases where the new text fits in. Volume 4 (especially chapter 2) contains entire sections of grey text. Consistency should be sought between all volumes and chapters to improve usability by inventory compilers		Noted	As clarified in the explanatory note which accompanied the Final Draft circulated for the final government review, after the adoption/acceptance by the Panel, the 2019 Refinement will be published without grey highlight. The purpose of grey highlight in the draft is solely to facilitate the review and the differences accross different chapters/sections reflect the "amount" of refinements proposed. Therefore, is expected that "sometimes there are entire sections of grey text, with a minor phrase or one to two new paragraphs (in white) included. Sometimes there is no grey text".
						United States of America		
2951	General	General			Maintaining the new text separate from the original 2006 Guidelines is not user friendly. It requires reading three documents at once: the relevant chapter in the 2006 Guidelines, the relevant chapter in the Refinement, and the annex mapping the relationship between sections. Far easier would be to incorporate the new text into the 2006 Guidelines in a new document, highlighting or underlining the new text. This would greatly assist not only review, but ultimately the likely uptake by inventory compilers.	United States of America	Noted	IPCC decided to prepare a "2019 Refinement to the 2006 IPCC Guidelines for National GHG Inventories" (2019 Refinement), which will not replace the 2006 IPCC Guidelines; it will be used in conjunction with the 2006 IPCC Guidelines. Consolidating all methodological guidance into a single report would require a new IPCC decision, subject to be discussed in the IPCC plenary.

CommentID	Volume	Chapter	Fromline	Toline	Comments	Country	Responses	Authors' notes
2953	General	General			Most new examples presented in the Refinement seem to come from A1 Parties. Using examples from a broader variety of Parties may help make the Refinement more accessible to a wider range of countries.	·	Noted	Efforts were made to include data and information from developing countries or non-Annex I counties under the UNFCCC, and a number of examples of such data/information were already included in the Final Draft. For example:
								- In Chapter 2 of Volume 4 (AFOLU), Box 2.0e (New Guidance) using a biomass map for GHG estimation: An Example from the Brazilian Amazon.
								- Volume 2 (Energy) has application for and draws emission factors from non-annex-1 countries at many places. For instance, the fugitive emissions from coal mining (section 4.1) where in data and emission factors include those from large developing countries; section 4.3.2.1 on charcoal and biochar production especially tables 4.3.2 and 4.3.3 (emission factors and uncertainty estimation), and Appendix 4a.2 (Fugitive Greenhouse Gas Emissions from Wood Pellet production).
						United States of America		Such efforts will be continuously made in the future work by TFI.
3851	General	General			Different land uses, such as agricultural, grassland, forest, etc may be used to produce bio-energy/fuel. In this refinement, the approaches of Greenhouse Gas emissions accounting in relation to bio-energy should be explained. Please consider including how double accounting is avoided.	Norway	Noted	Treatment of CO2, CH4 and N2O emissions from combustion of biomass or biomass-based products is explained in detail in Chapter 1 of Volume 1. By this, and also by relevant guidance given in relevant chapters in sectoral volumes, the final draft of 2019 Refinement already provides guidance to avoid double counting of GHG emissions within a country's inventory.
289		Overview_Ch		277	We suggest that this paragraph briefly highlight some of the other specific developments in Chapter 2 of Volume 4 of the 2019 Refinement 2019, in particular on the consistency between AFOLU projects or activities and the IPCC inventory guidelines (Box 2.0A), on the use of allometric models for biomass estimation (Section 2.3.1.3.3.A) and on additional generic guidelines for Tier 3 methods (Section 2.5). These developments are particularly relevant for the implementation and improvement of reporting for all countries.	France	Accepted with m	The discussion about consistency in AFOLU projects and the inventory guidelines is provided for information purpose in a box and it is not guidance, so it is not appropriate to highlight it here. Highlight on allometric equations is already included in the bullet on "bimass estimates". A new bullet on Tier 3 model has been added.
593	Overview_C	Overview_Ch	78	78	Delete "Thailand" from the end of the line	New Zealand	Accepted	
595	Overview C	Overview_Ch	163	166	Not clear if the table in Box 2 is supposed to be complete - it isn't; but this is OK if the intent is to only have part of the table for illustrative purposes	New Zealand	Noted	The intent is to only have part of the table for illustrative purposes, indeed. Therefore the title clearly says it is just an example, which shows readers what to find inside the the volumes of the 2019 refinement.

								managed land proxy in addition to a method for factoring out.
								In fact, we have included the factoring out method because it
								was specifically requested in the TOR from the IPCC panel to
								the authors for this report. Both total emissions using the MLP
								and net emissions from factoring out are reported based on the
								reporting tables that we have provided. We have revised the text to state that for transparency, it is good practice to report
								both the total emissions and net emissions if net emissions are
								estimated; otherwise the country should only report total
								emissions if net emissions are not estimated.
								emissions if flet emissions are not estimated.
								The method is based on science and the methods provided in
								the IPCC guidance. It has been well-established in the scientific
								literature that non-saline water bodies and wetlands emit CH4
								when they are unmanaged. Conversion of unmanaged
								wetlands or water bodies to flooded lands does increase the
								emissions, but a portion of these emissions would continue to
					As reflected in our comments on Volume 4 Chapter 7, we have strong			occur if the land was not converted to flooded land, and this
					concerns about the proposals to factor out emissions and removals that			portion is factored out. In contrast, unmanaged forest land and
					would have otherwise occured in the absence of flooding (i.e., converting			grassland are typically a sink for CH4, and the net flux is
					unmanaged land to managed by flooding). This approach contradicts the			considered non-anthropogenic even for managed forest land
					principles behind the managed land proxy. Based on the information			and grassland. Therefore there is no need for guidance to
